Investigations—Microscopy and bacteriology of the stools were normal. Sigmoidoscopy and a barium enema were also normal Radiography of the chest showed normal heart and lung fields A blood count showed Hb 87% (12 9 g per 100 ml), red cells 4 430,000 per c.mm., and white cells 10 600 per c.mm. (neutrophils 68%, lymphocytes 31%, monocytes 1%) On May 26, 1949 the blood chemistry (in mg or g per 100 ml. or m.eq per litre of serum) was sodium 301 mg (103 5 m eq), potassium 12 1 mg (3 1 m.eq), chlorides (as sodium chloride) 600 mg (102 6 m eq), calcium 7 6 mg (1 9 m eq) phosphorus 3 2 mg (1 0 m.eq), bicarbonate 69 ml CO_2 (30·8 m eq), protein 6 1 g (albumin globulin ratio = 1 3 1), urea 28 mg The electrocardiograms showed changes related to the serum-potassium level and are reported elsewhere (McAllen 1951)

Progress—The diarrhœa continued unchecked for three weeks after admission, despite routine treatment with fluids

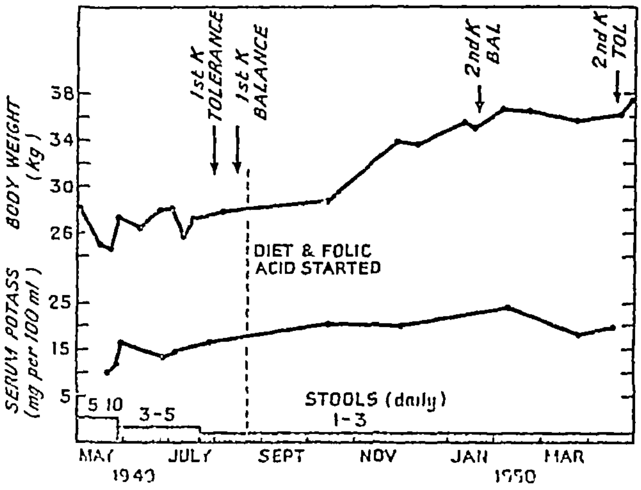

Fig 1—Serum potassium level and weight before and during treatment.

sulphaguanidine, kaolin, and vitamins There was a little improvement in the patient's condition during the next two months A three day fat balance test (233 g of fat taken) showed 77 7% absorption The fæcal nitrogen averaged 0 98 g a day A fractional test meal revealed a histamine fast achlorhydria The glucose tolerance curve after glucose 50 g by mouth was low and flat (80, 67, 83, 67, 60, 67 mg per 100 ml at half hourly intervals) A barium meal showed a pronounced deficiency pattern in the small intestine The diagnosis of steatorrhœa was thus established, and the evidence was in favour of the idiopathic type Treatment with a low fat high protein diet and folic acid 20 mg was then started There was a great improvement in the patient's condition over the next six months (fig 1) Her weight increased by 12 kg and she became more alert mentally Her tongue and lips returned to normal The frequency of her stools decreased to 1–3 a day The serum potassium level rose to 23 mg per 100 ml A second barium meal showed a normal pattern in the small intestine A glucose tolerance test gave a normal result (82, 124, 92, 76, 86, 68 mg per 100 ml) The fat balance, however, remained abnormal, showing 74% absorption

Electrolyte Studies —The first study was carried out during the acute phase of the illness, before the treatment by diet and with folic acid had been given Potassium and sodium were in great excess in the fæces, and there was a negative balance of each The second study, during the clinical remission following treatment, showed almost normal values of potassium and sodium in the fæces and a positive balance of each The results are shown in the accompanying table

Potassium tolerance Tests —Oral potassium tolerance tests were made during the acute and remission phases (fig 2) The serum potassium level was determined before, and at intervals after, the patient had been given potassium chloride 5 g by mouth The two curves are strikingly different The second (remission phase) agrees in shape with the normal curves described by Zwemer and Truszkowski (1936), Keith et al (1942), and Keith and Osterberg (1946) The first (acute phase) shows a delayed rise to a low maximum, followed by a slow fall

POTASSIUM AND SODIUM BALANCES IN ACUTE AND REMISSION PHASES

—	Amount of potassium or sodium (g per 24 hr)			
	Acute phase		Remission phase	
	Pot	Sod	Pot	Sod
Intake	3 0	1 4	3 0	3 4
Excretion				
In fæces	4 9	1 3	0 6	0 1
In urine	1 7	0 6	1 5	2 3
Balance	−3 6	−0 5	+0 9	+1 0

During both balances the patient was on a constant intake of potassium and sodium for three days before collections began The first balance period was over 24 hours the second over 72 hours

DISCUSSION

In this case there was no evidence of associated or underlying disease which could have given rise to the high fæcal potassium level during the acute phase Increased cellular loss from the bowel, as a cause, was excluded by the normal fæcal nitrogen level. The high fæcal potassium level could be explained by a defective absorption of potassium from the diet and the intestinal secretions, in view of the many absorption defects which are believed to occur in steatorrhœa This explanation is supported by the initial low flat potassium tolerance curve and by its change to a normal shape after the patient had responded clinically to treatment

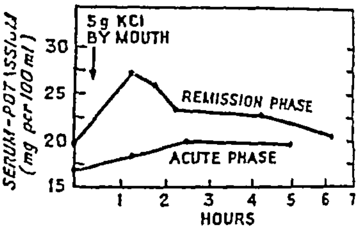

Fig 2—Potassium tolerance tests during acute and remission phases

SUMMARY

A case of idiopathic steatorrhœa is described which showed a low serum potassium level, excessive loss of potassium in the fæces, and a negative potassium balance

The potassium deficiency was thought to be caused by impairment of potassium absorption

We wish to thank Dr N F Coghill for permission to study this case, and Mr R J Hall for technical assistance

PROLONGED ABNORMALITY OF CEREBROSPINAL FLUID AFTER CISTERNAL STREPTOMYCIN

DAVID BEYNON
M B Lond , M R C.P , D C H
LATE RESIDENT ASSISTANT PHYSICIAN, THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND STREET, LONDON

A BABY, aged 6 weeks, was treated for acute meningitis due to *Bact fæcalis alkaligenes* with cisternal and intramuscular streptomycin The cerebrospinal fluid (C.S.F) became sterile on the second day of treatment, and clinical recovery was rapid, but six months passed before the protein content of the C S F returned to normal. The patient, now aged 2½ years, appears normal and mentally forward

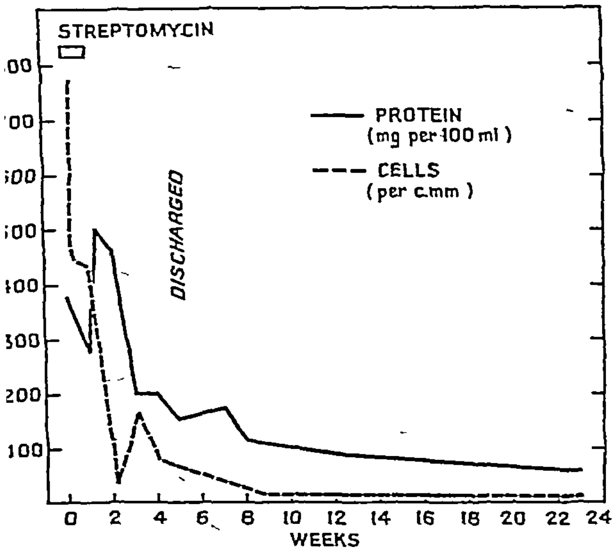
CASE RECORD

A baby girl, aged 6 weeks, was admitted to the Hospital for Sick Children, Great Ormond Street, with a history of loose stools and anorexia for five days and convulsions for four days

On admission she was ill, collapsed, and somewhat dehydrated, with rectal temperature 98°F, and weight 6½ lb There were constant fibrillary twitching of the left eyelids, spastic rigidity of the left leg and intermittent generalised convulsions *No neck rigidity was present*, and bulging of the fontanelle only appeared two days later when hydration had been fully restored Lumbar puncture on admission produced a dry tap, and cisternal puncture produced only a few drops of thick purulent fluid containing protein 384 mg per 100 ml sugar 6 mg per 100 ml, chlorides 540 mg per 100 ml, cells 3000 per c.mm (polymorphs 98%) A film of the C.S.F. showed many gram negative organisms, and a culture grew *Bact fæcalis-alkaligenes* A blood count showed 50,200 white cells per c mm (polymorphs 76%) A blood culture did not grow the organism

Treatment —Intramuscular penicillin and oral sulphadiazine were started on admission and continued for ten days From the day following admission streptomycin sulphate was given intrathecally 0 05 g daily for eight days and intramuscularly 0 04 g six hourly for seven days (0 02 g per lb of body weight daily) The intrathecal streptomycin dissolved in 5 ml of physiological saline solution was injected by cisternal puncture each day owing to continued lack of flow of C.S.F. on lumbar puncture, presumably due to spinal block Even cisternal puncture, on two occasions, produced only a few drops of thick purulent fluid, and streptomycin had to be injected under pressure

Progress —The C.S.F. was sterile on the day after streptomycin was started and remained so thereafter The turbid fluid became clear and yellow after three days Clinical improvement was obvious on the fourth day of treatment convulsions and twitching had stopped, the fontanelle was normal, and the appetite was good This progress was maintained until the seventh day of treatment, when a mild clinical relapse occurred Convulsions reappeared the fontanelle became tense, there was slight neck stiffness, and feeds were refused There was no corresponding change in the C.S.F. and the white-cell count in the blood continued to show steady improvement, being now 14 700 white cells per c.mm. (polymorphs 48%) It was therefore decided to stop intramuscular streptomycin on that day and the intrathecal streptomycin was stopped on the following day On the day after that the baby again rapidly improved and no further ill effects appeared She gained weight steadily and was discharged home in the fifth week.



Alterations in cerebrospinal fluid

Follow up —When the patient was discharged from hospital the C.S.F. still contained 154 mg protein per 100 ml. and 61 white cells per c mm She was therefore subsequently readmitted at intervals for lumbar puncture The C.S.F. white-cell count fell to normal in the eighth week after the illness, but the protein was still 60 mg per 100 ml after twenty three weeks (see figure) Six months after this a lumbar puncture produced C.S.F. which was chemically normal, with protein 30 mg per 100 ml Clinically the child has remained quite well and her mental and physical development has been forward rather than average Her mother said that she spoke her first word at the age of 7 months and began to walk at 11 months Now at the age of $2\frac{1}{2}$ years she is a healthy child, with no detectable abnormality of the nervous system. Her hearing and eyesight appear normal to clinical testing, and there is no ataxia The circumference of her head is $19\frac{1}{4}$ in (average = 19 in) Her mother considers that she is mentally more forward than was her elder sister at the same age

DISCUSSION

Bact fæcalis alkaligenes is a harmless saprophytic inhabitant of the gastro intestinal tract, and only very rarely becomes pathogenic Bischoff et al (1948) found only six previously published cases of meningitis due to this organism They described two further cases, both fatal, in newborn babies The results of treatment of four cases with streptomycin have been reported (National Research Council 1946), with one survival

The protracted high protein level and raised white cell count of the C.S.F. in the present patient are presumed to be a direct toxic effect of the streptomycin A relatively large dose of streptomycin for an infant of this size was injected daily for eight days into the cisternal space It is interesting that the protein level rose suddenly from about 280 to 600 mg per 100 ml. on the third day after streptomycin had been stopped Cathie (1948) has demonstrated the effect on the cells and protein of the injection of streptomycin into a normal theca, his figures show an immediate cellular response but a delayed small rise in protein level Ounsted (1949), describing the treatment of ten cases of *Hæmophilus influenzæ* meningitis with streptomycin, reports that the C.S.F. in several cases remained mildly abnormal for ninety days after the institution of treatment No such abnormality has been described after other forms of treatment Examination of the records of twenty cases of acute meningitis due to various organisms successfully treated with intrathecal penicillin and/or oral sulphonamides at this hospital showed no prolonged abnormality of the C.S.F. beyond six weeks

The clinical relapse which occurred on the seventh day of treatment is considered to be significant There was a pronounced rise of intracranial pressure without any corresponding change in composition of the C.S.F. It is suggested that there was an increased secretion of C.S.F. due to irritation of the choroid plexuses by the streptomycin

Attention has already been drawn to clinical reactions following cisternal and intraventricular injection of streptomycin (Cathie 1948, Debré and Mozziconacci 1949) A report on the treatment of tuberculous meningitis (Smith et al 1948) describes an acute hydrocephalic episode which arose during the course of streptomycin treatment in two cases, and another (Medical Research Council 1948) describes dramatic clinical improvement, with cessation of meningism, in two cases when streptomycin was stopped Two of Ounsted's (1949) patients with *H influenzæ* meningitis were given intraventricular streptomycin because of spinal block. One, a baby aged 10 months, died from an acute hydrocephalic attack on the day following the first injection The other, aged 9 months, was given intraventricular streptomycin for three days and then lumbar injection for twelve days Four days after intrathecal streptomycin had been stopped the baby had an attack resembling a hydrocephalic attack This was attributed to a probable intercurrent infection, but the C.S.F. remained sterile; there was a slight rise in the protein level but none in that of the cells

It is suggested that streptomycin, when injected intracranially, can produce an increased outflow of C.S.F. sufficient to cause signs and symptoms of raised intracranial pressure, thereby disguising the clinical course of the disease and raising the hazard of overtreatment

SUMMARY

A case is described of severe acute meningitis due to *Bact fæcalis-alkaligenes*, a very rare and fatal infection, in a baby aged 6 weeks

Treatment was with streptomycin, cisternal as well as intramuscular, because of spinal block

Recovery was rapid, but a mild abnormality of the C S F in the form of raised protein level persisted for over twenty three weeks

This is considered to be a direct toxic effect of streptomycin, but has been without any ill effects on the patient, as judged by clinical examination after an interval of nearly two and a half years

A possible effect of streptomycin in producing raised intracranial pressure is also discussed

I wish to thank Dr Bernard Schlesinger, under whose care this patient was treated for permission to publish, and Dr I A B Cathie for advice and for pathological reports

GALL-BLADDER DISEASE IN CHILDHOOD

ROLAND N JONES
M A, M Chir Camb, F R C S
CHIEF ASSISTANT, ESSEX COUNTY HOSPITAL,
COLCHESTER

DISEASE of the gall bladder in children is not commonly recognised, for Kellogg (1923) could only collect 64 cases published in the last 200 years These cases include cholecystitis alone, cholelithiasis alone, and, more often, the two in combination Potter (1928) collected and summarised 226 cases, and Sobel (1938) increased the total to 317 The incidence is higher in males, and calculi have been found in an eight month fœtus

The first reported case was under the care of Joseph Gibson, a surgeon of Leith (Swing and Bullowa 1938)

A boy, aged 12, fell sick with severe right-sided abdominal pain in October, 1721, and his condition deteriorated until death 18 months later He had hectic fever and vomited frequently After a few months the stools were white, and a mass appeared in the right hypochondrium, emaciation was conspicuous *Œdema and ascites appeared towards* the end of the illness, and two days before death 12 lb of turbid greenish fluid was removed by paracentesis

Gibson was assisted in the necropsy by James Crawford, professor of medicine, and also of Hebrew, in the University of Edinburgh The report says that 'the gall bladder was extended to a most surprising Bulk, for it contained no less than two Scots Pints, or eight pounds of Bile ' The wall was thickened, and the common duct was dilated and contained small spongy yellow stones When the slightly enlarged liver was cut, "a great number of spherical Tubercles, about the Bigness of a common Bean appeared in its Substance, some of the Gentlemen present were inclined to esteem them to be Glands, but how justly I am not to determine It was observ ed *that they had no vessels either entering in or growing* out of them, and seemed only to be set loose in the Substance of the Liver ' These were undoubtedly multiple liver abscesses resulting from ascending cholangitis and stones in the common duct

Acute cholecystitis, uncomplicated by stone, is usually due to bacterial infections, such as typhoid, septicæmia, and scarlet fever In children the migration of intestinal parasites, such as ascaris and protozoa, is not ordinarily accompanied by inflammation, though this is common in adults On the other hand, acute suppuration of the bile ducts and gall bladder *may* be set up by *round* worms entering the bile passages from the intestine Disease of the gall bladder is often confused with appendicitis, and often there is 5–10 years' history of undiagnosed attacks of abdominal pain (Sobel 1938) Evarts Graham is of the opinion that many cases of cholecystitis first recognised later in life had their origin in childhood, when they were regarded as catarrhal jaundice, gastroenteritis or indigestion Cholecystitis may be associated with mild inflammation of the appendix, and it has been suggested that cholecystitis may be a metastatic complication of an acute or chronic appendicitis (Farr 1922, Snyder 1925)

The primary complaint is abdominal pain, varying in intensity and usually in the right hypochondrium Many workers emphasise the fact that the pain is in the region of the umbilicus and radiates to the right subcostal angle (Lowenburg and Mitchell 1938) Nausea and vomiting are common, with pyrexia and often jaundice There is usually a moderate leucocytosis In cases associated with mild changes in the appendix the pain is often localised in the right iliac fossa

The treatment seems to depend on whether exploration has been carried out for appendicitis If disease of the gall bladder has been diagnosed, penicillin and sulphonamides should be used before having recourse to surgery (Nelson 1946) Surgical *treatment* consists in drainage or cholecystectomy

CASE RECORD

A female child, aged 3 years *was admitted* with 48 hours history of abdominal pain At the onset she appeared fretful and complained of pain in the lower abdomen on being lifted from her cot She vomited twice during the first night, but next day she seemed better however she was kept in bed During the following night she became restless, cried, and again appeared to have pain in the lower abdomen, though she did not vomit again *Her bowels were regular* but on the day of admission her stools were said to have been rather pale

On examination she was well nourished, with a flushed face and circumoral pallor There was rigidity with tenderness over the whole abdomen, especially on the right side, and she appeared to be in much pain Rectal examination revealed no abnormality, and no abnormal physical *signs* were found in the chest Acute appendicitis was diagnosed and operation undertaken forthwith

Operation —The appendix was approached through a muscle splitting incision in the right iliac fossa, and, when the peritoneum was opened, a thin purulent fluid *welled out* of the abdominal cavity The appendix was readily delivered and found to be *normal*, *it was removed, but* on exploration of the abdomen through this incision a very large tense gall-bladder was palpated which was dusky purple all over It could not be emptied by light pressure, and the omentum was slightly adherent to it The incision in the right iliac fossa was closed, and cholecystectomy was done *through* a right upper paramedian incision No anatomical abnormality of the biliary system was *found* The abdomen was closed, and the child returned to the ward

The gall bladder was $3^1/_2$–4 in long, and its entire surface was purplish and covered with fibrin It could not be emptied by pressure even after removal, and the obstruction proved to be due to an enlarged cystic gland The mucosal surface was covered with hæmorrhagic areas, and the wall appeared very thin in places On being opened it was found to be filled with a greenish flocculent fluid, undoubtedly containing pus Unfortunately no culture was made The diagnosis of acute cholecystitis was confirmed microscopically

Progress —The child passed a satisfactory night after *operation but next day seemed to* have profound toxæmia, with cyanosis, rapid respirations, vomiting, and a rapid thready pulse Continuous gastric suction was instituted, an intravenous glucose drip was started, and *half* a pint of blood was transfused The child improved slowly for 48 hours and from then onwards *made an uninterrupted* recovery She was discharged from hospital 28 days after admission

COMMENTS

This case has many points of interest, for it presented as an acute appendicitis, which was quite properly submitted to operation, when a general acute peritonitis was discovered The gall bladder was distended and tense, seemed to be in danger of perforating, and, if left, might easily have done so Even if the correct diagnosis ad been made in this case, it would have been dangerous o treat the condition without operation With severe bdominal pain in childhood, when a confident diagnosis as not been made, it is wiser to "look and see" than to wait and see"

Acute cholecystitis in children should be treated by holecystectomy, but, if the child appears too ill for hat, cholecystotomy should be done, followed by holecystectomy later

It is well to remember gall bladder disease in the liagnosis of abdominal pain in children, and, if laparo-omy is done and a normal appendix and no obviously nlarged abdominal glands are found, the gall bladder hould be examined

TREATMENT OF ACUTE LEUKÆMIA WITH AMINOPTERIN

JOHN F WILKINSON
M.D, M Sc, Ph.D Manc, F.R C.P, F R I C
PHYSICIAN AND DIRECTOR, DEPARTMENT OF HÆMATOLOGY

C GARDIKAS
M D Athens, M Sc, Ph.D Manc
REGISTRAR

MANCHESTER ROYAL INFIRMARY

IN 1948 Farber et al noted the beneficial effects of olic acid antagonists on acute leukæmia in 50% of a group of children, various degrees of temporary improvement were noted during therapy with aminopterin or other folic-acid antagonists, such as amethopterin, Amino an fol,' 4-amino N¹⁰ methyl pteroylglutamic acid or 4-amino pteroylaspartic acid Later Farber (1949) reported that in 2 patients clinical and hæmatological remissions were sustained for sixteen and twenty three months, both patients being alive at the time he wrote

Several other workers have also observed the effects of folic acid antagonists in the treatment of acute leukæmia thus Dacie et al (1950) obtained various temporary remissions in 9 out of 13 patients with acute leukæmia, Dameshek (1949) in 9 out of 35, Jacobson et al. (1948) in 2 out of 10, Jimenez de Asua (1949) in 3 out of 8, Meyer et al (1949) in 2 out of 37, and Pierce and Alt (1948) in 5 out of 9 cases Sachs et al (1950) observed a considerable improvement in 2 of 14 children, and Stickney et al (1948, 1949) in 54 cases of acute leukæmia treated with folic acid antagonists reported 8 cases of complete remission, the word "complete" is used in the sense that both clinical and hæmatological (blood and/or marrow) pictures improved. A complete remission was also observed by Hart (1949) in 1 case of monocytic leukæmia Another 58 cases, with remission in 19, are mentioned in an extensive review on the subject by Thiersch and Philips (1949), according to whom about 250 cases of acute leukæmia in man have so far been treated with folic acid antagonists with temporary remissions in about 30% This percentage is much above the spontaneous remission-rate reported by Diamond and cited by Farber (1949) as approximating to 10%

Between December, 1948, and August, 1950, we treated 27 patients with acute leukæmia with the folic acid antagonist aminopterin, and we summarise our results here

MATERIAL AND TECHNIQUE

There were 14 adults and 13 children—20 males and 7 females In all cases the diagnosis of acute leukæmia was established by marrow biopsy, although the type of the dominant cell could not always be determined with certainty However, on the basis of the cytologic appearances they were classified as 19 cases of acute myeloid leukæmia, 5 of acute lymphatic leukæmia, and 3 of acute monocytic leukæmia

Aminopterin only was given to all the patients in this group except one who had previously received 'Met Fol B,' but this was superseded later by aminopterin The usual plan of treatment has been to give intramuscular aminopterin 1 mg daily or on alternate days, but this was always discontinued or given at less frequent intervals if any toxic manifestations or severe leucopenia developed Blood transfusions and antibiotics were given if the patient's condition required them, otherwise no other treatment was given

RESULTS

For the purpose of tabulation we have used criteria similar to those of other investigators Thus, partial remission is used to imply that the clinical condition showed subjective improvement with return to normal temperature and decrease in size of lymph-nodes and spleen, but the hæmatological picture either remained unchanged or the white cell count fell to normal limits although the numbers of immature cells might remain unmodified Complete remission implies both clinical improvement and remission of the hæmatological condition

In 6 cases the patient received less than 3 mg of aminopterin because the treatment was instituted at very advanced terminal stages of the disease, the patients dying before larger doses of aminopterin could be given, or because it was necessary to discontinue this treatment owing to the onset of a severe leucopenia or other severe toxic manifestation that might have been due to the aminopterin

Tables I and II give the results of the treatment in the other 21 cases No remission was maintained for long, since the marrows of all patients now alive are leukæmic

As table II shows, there were only 2 patients in whom a complete remission was brought about, one of them is given in detail since it presented interesting features

CASE 12

A girl, aged $2^1/_4$ years, entered the hospital on June 15, 1949, almost moribund She had been well until two months

TABLE I—PATIENTS WHO SHOWED NO RESPONSE TO AMINOPTERIN

before admission, when she developed a swelling of the neck. The swelling subsided within a week, and the patient was moderately well until five weeks before admission. Since then she had been weak and pale, and because these symptoms became progressively worse she was admitted on May 15, 1949, to another hospital. A blood count and sternal puncture were done and acute leukæmia was diagnosed. She was discharged from the other hospital thirteen days before the present admission under our care.

On admission she was very ill, lethargic, pale, and dyspnœic. The cervical, axillary, and inguinal lymph nodes were slightly enlarged. The spleen was just palpable. The remainder of the examination was essentially negative. A blood count showed red cells 1,750,000 per c mm, platelets 28,000 per c mm, Hb 30%, white cells 377,000 per c mm (polymorphs 2·0%, lymphocytes 6·5%, monocytes 1·0%, "blasts" 90·5%). The bone marrow was packed with blasts (99%).

Course.—On the same day aminopterin treatment was started. By the fourth injection the patient's condition showed a remarkable improvement, and five more injections, each of 1 mg of aminopterin, were given. Four weeks after the institution of the treatment the improvement was most striking, and from that time (July 20) until the beginning of September, 1949, the child appeared well. Her appetite had improved, weight increased, and peripheral blood so improved that the red cells numbered 3,500,000–3,800,000 per c mm, Hb was 65–85%, and white cells numbered 5000–7000 per c mm, with a completely normal differential count. The blood picture on Aug. 24, 1949, showed red cells 3,890,000 per c mm, Hb 86%, and white cells 8000 per c mm (polymorphs 54·0%, lymphocytes 45·0%, blasts 1·0%). A sternal marrow biopsy showed that the bone marrow picture also was completely normal.

On Sept. 10, 1949, the child started to relapse. A blood count on Sept. 14 showed red cells 4,050,000 per c mm, Hb 50% and white cells 389,000 per c mm (polymorphs 1·5%, lymphocytes 88·5%, blasts 10·0%, platelets 12,000). Sternal puncture showed a bone marrow again packed with blasts. The child was readmitted to hospital and had a second course of aminopterin, consisting of five daily injections of 1 mg each. The response to this second course was again remarkable, and the child remained well for two months. During the second remission the red cells numbered 3,500,000–4,500,000 per c mm, Hb was 70–90% and white cells 4000–7200 per c mm, the differential count being essentially normal. On Oct. 31, 1949, a blood count showed red cells 3,620,000 per c mm, Hb 70%, white cells 7200 per c mm (polymorphs 66·5%, lymphocytes 22·5%, monocytes 10·0%, blasts 1·0%), and platelets 300,000 per c mm. On Oct. 21, 1949, sternal puncture showed that the bone marrow was normal, both myeloid and erythroid series appeared active.

The patient was discharged on Nov. 18, 1949, but readmitted on Dec. 20, 1949, because she was not at all well. She was very pale, had nodules in the scalp and a few small lymph nodes in the cervical region, and her spleen was palpable 6 cm below the costal margin. From that time onwards the course was progressively downhill, and she died on Jan. 17, 1950, without any further remission. The accompanying figure shows the course of the disease.

Necropsy showed gross hæmorrhage into the right internal capsule and had ruptured into the ventricular system; there was considerable subtentorial clot around the pons and medulla.

The interest of this case lies in the fact that aminopterin induced two dramatic complete, although temporary, remissions from both the clinical and the hæmatological aspects. All bone marrow and peripheral blood films were practically normal during the short remissions, and the child appeared entirely normal clinically.

TOXIC SYMPTOMS

The toxic symptoms produced by aminopterin have been similar to those reported by others, and in 13 of our patients were as follows:

Stomatitis	3	Other types of rash	1
Diarrhœa	2	Epistaxis	[illegible]
Hæmorrhagic rash	3	Alopecia	[illegible]

In many instances it has been difficult to assess whether aminopterin and not the leukæmic process should be held responsible for certain of these manifestations. Wide fluctuations in the number of leucocytes are often seen in acute leukæmia; it is often impossible to be certain whether, for instance, severe leucopenia or thrombocytopenia are toxic symptoms due to the aminopterin or merely features known to occur in the terminal phase of acute leukæmia. Discontinuance of treatment may often be followed by remission of the toxic symptoms.

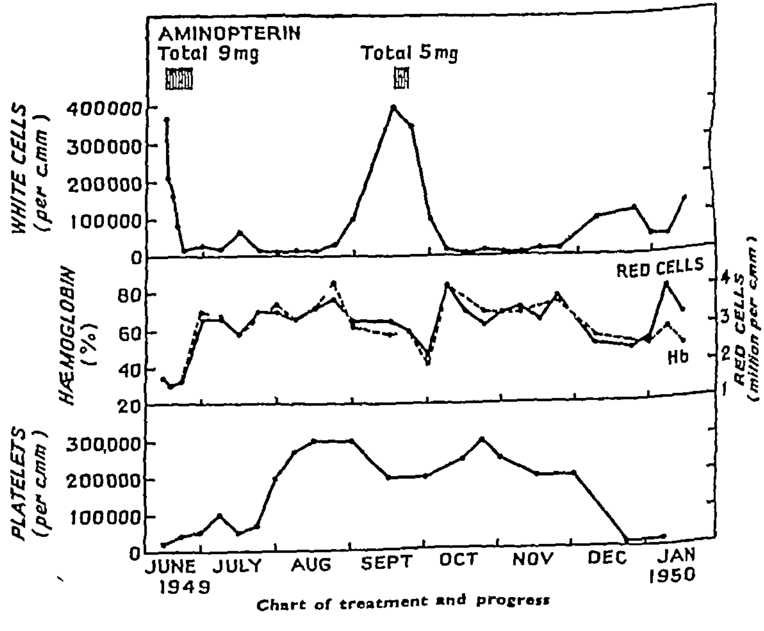

Chart of treatment and progress

DISCUSSION

The ultimate results obtained by the use of the folic acid antagonists in the treatment of acute leukæmia have so far been unsatisfactory In most patients these substances have not affected the leukæmic process to any extent, the course of the disease progressing steadily Experience has shown that the use and control of the effects of these substances is not easy for their effects in any given case are unpredictable Toxic manifestations may be numerous, and often come on with dramatic suddenness, for the margin between the therapeutic and the toxic dosages is extremely small Consequently, the use of these substances in the treatment of acute leukæmia must be restricted, they should only be used by those fully familiar with their effects and having full hæmatological facilities for the daily control that is necessary in the beginning Nevertheless, the frequent observations that some patients show complete or almost complete, although temporary, clinical and hæmatological remissions have renewed hope for future treatment of the hitherto invariably fatal acute leukæmias It is of the greatest importance that even in a proportion (greater than the spontaneous occurrences) of acute leukæmias, many of which are certainly of different ætiology, remissions can be produced for a time by known chemical agents Quite clearly much further work is required to separate the group, or groups, of acute leukæmias that may be sensitive to this form of therapy, and to follow up the clues already appearing so as to develop more suitable and less toxic chemical substances A greater proportion of acute leukæmias do not show any beneficial response to these agents, and probably fall into other groups of different ætiology, just as the chronic leukæmias do For them other types of chemical agents are required

SUMMARY

27 patients with acute myeloid, lymphatic, or monocytic leukæmia were treated with aminopterin

6 patients received less than 3 mg of aminopterin because either the treatment had to be discontinued after development of severe leucopenia or had been instituted at a very advanced stage, the patient dying before further doses could be given

Of the remaining 21 patients, the treatment produced no response in 15, partial remissions in 4, and complete remissions in 2 for relatively short periods

One case is reported to demonstrate the ability of aminopterin to induce two dramatic complete remissions in which the clinical condition, the hæmatological picture, and the bone marrow returned to normal

We wish to thank the Medical Research Council for a research grant, the Sybil Mary Pilkington Fund Trustees for a fellowship to one of us (C G), and Messrs Lederle Laboratories Division, American Cyanamid Company, for supplying the aminopterin free both directly and through the Medical Research Council

THE DANGER OF PENICILLIN THERAPY IN GONORRHŒA

A A M REEKIE
M.B Edin

PHYSICIAN I C VENEREAL DISEASE DEPARTMENTS, PRINCE OF WALES'S HOSPITAL, LONDON ASHFORD HOSPITAL, MIDDLESEX, AND MILLER GENERAL HOSPITAL, GREENWICH

THE treatment of gonorrhœa with penicillin has increased the risk that concomitant syphilis may go unrecognised

The incubation period of syphilis (9–90 days, average 3 weeks) being so much longer than that of gonorrhœa (12 hours–21 days or more, average 2–5 days), in simultaneous infections the gonococcal urethritis is being treated while the patient is in the incubation period of syphilis The small doses of penicillin which are so successful in curing acute gonorrhœa may suppress or modify primary or early generalised symptoms and signs of concomitant syphilis without curing it (Shafer and Zakon 1944, Camzares 1944, Hailey 1944, Ricchiuti 1944, Boyd et al 1944, Walker and Barton 1945, Kemp and Shaw 1946, Leifer and Martin 1946, Suter 1947)

The early treatment of syphilis decreases the opportunity for dissemination of infection both in the individual and in the community and appreciably increases the probability of cure (Moore 1948) Double infection is not uncommon—males 1 4%, females 3% (Kemp and Shaw 1946)—and whenever it is suspected the gonorrhœa should be treated not with penicillin but with another drug, such as sulphonamide which will not prevent syphilis from declaring itself

SIGNIFICANCE OF PYREXIA

Ricchiuti (1944), Walker and Barton (1945), Fromer et al (1946), and Leifer and Martin (1946) mention the development of chills, fever, and malaise, developing early in the course of penicillin therapy of gonorrhœa, as a possible indication of dual infection

The treatment of early syphilis with penicillin is accompanied by a Herxheimer reaction in 50–90% of cases (Moore 1949, Leifer and Martin 1946, Fromer et al 1946) The reaction is attributed to the liberation of toxins from the spirochætes either dead or in course of destruction by penicillin It is in fact therapeutic shock, and it may be systemic and/or focal It occurs with a penicillin dosage of 10 units per kg of body weight, or more, it usually appears from three to nine hours after the initial dose of penicillin and its incidence and severity are not related to dosage (above 10 μ per kg of body weight), or stage or duration of infection (Moore 1949) In early syphilis fever is almost an essential part of the reaction

Penicillin treatment of uncomplicated gonorrhœa, on the other hand, is very rarely accompanied by fever Leifer and Martin (1946) state that they have not observed fever "among hundreds of cases" Buchholtz (1946) says that, in the penicillin treatment of over 2000 patients with simple acute or chronic gonococcal urethritis unaccompanied by clinical evidence of syphilis, only 2 or 3 patients were observed to have a febrile reaction which could not be explained either by a toxic reaction to penicillin or by the coexistence of syphilis

Therefore unexplained fever and malaise during the early stage of penicillin therapy in acute gonorrhœa strongly suggest concomitant syphilis

ILLUSTRATIVE CASE RECORDS

Case 1 —A lorry-driver, aged 26 reported in February, 1948, with 4 days history of urethral discharge He had had gonorrhœa 9 months previously treated in London. Recent exposures had been 1 4, and 8 weeks previously with different consorts no precautions had been taken at the last two The urethral discharge was diagnosed

TABLE II—PATIENTS WHO SHOWED PARTIAL OR COMPLETE REMISSION FOLLOWING AMINOPTERIN TREATMENT

Case no	Sex	Age (yr)	Length of treatment (days)	Total dose (mg)	Length of remission (days)	Duration of leukæmia since treatment began (days)	Type of leukæmia
				Partial remission			
16	M	6	25	17	20	75	Myeloblastic
17	M	13³/₄	25	Met Fol B 100 mg + aminopterin 6 mg	60	120	Myeloblastic
18	M	4	10	3	20	60	Myeloblastic
19	M	5¹/₂	28	14	60	204	Monocytic
				Complete remission			
20	M	15	51	15	30	63	Myeloblastic
21	F	2¹/₄	2 courses {17 15	2 courses {9 5	2 remissions {62 60	167	Lymphatic

before admission, when she developed a swelling of the neck The swelling subsided within a week, and the patient was moderately well until five weeks before admission Since then she had been weak and pale, and because these symptoms became progressively worse she was admitted on May 15, 1949, to another hospital A blood count and sternal puncture were done and acute leukæmia was diagnosed She was discharged from the other hospital thirteen days before the present admission under our care

On admission she was very ill, lethargic, pale, and dyspnœic The cervical, axillary, and inguinal lymph nodes were slightly enlarged The spleen was just palpable The remainder of the examination was essentially negative A blood count showed red cells 1,750,000 per c mm, platelets 28 000 per c mm, Hb 30% white cells 377,000 per c mm (polymorphs 2 0%, lymphocytes 6 5%, monocytes 1 0% "blasts" 90 5%) The bone marrow was packed with blasts (99%)

Course—On the same day aminopterin treatment was started By the fourth injection the patient's condition showed a remarkable improvement, and five more injections, each of 1 mg of aminopterin, were given Four weeks after the institution of the treatment the improvement was most striking, and from that time (July 20) until the beginning of September, 1949, the child appeared well Her appetite had improved, weight increased, and peripheral blood so improved that the red cells numbered 3,500,000–3,800,000 per c mm, Hb was 65–85%, and white cells numbered 5000–7000 per c mm, with a completely normal differential count The blood picture on Aug 24, 1949, showed red cells 3,890,000 per c mm, Hb 80%, and white cells 8000 per c mm (polymorphs 54 0%, lymphocytes 45 0%, blasts 1 0%) A sternal marrow biopsy showed that the bone marrow picture also was completely normal

On Sept 10, 1949, the child started to relapse A blood count on Sept 14 showed red cells 4,050,000 per c mm, Hb 50% and white cells 389,000 per c mm (polymorphs 1 5%, lymphocytes 88 5%, blasts 10 0%, platelets 12,000) Sternal puncture showed a bone marrow again packed with blasts The child was readmitted to hospital and had a second course of aminopterin, consisting of five daily injections of 1 mg each The response to this second course was again remarkable, and the child remained well for two months During the second remission the red cells numbered 3,500,000–4,500,000 per c mm, Hb was 70–90%, and white cells 4000–7200 per c mm, the differential count being essentially normal On Oct 31, 1949, a blood count showed red cells 3,620,000 per c mm, Hb 70%, white cells 7200 per c mm (polymorphs 66 5%, lymphocytes 22 5%, monocytes 10 0%, blasts 1 0%), and platelets 300,000 per c mm On Oct 21, 1949, sternal puncture showed that the bone marrow was normal, both myeloid and erythroid series appeared active

The patient was discharged on Nov 18, 1949, but readmitted on Dec 20 1949, because she was not at all well She was very pale, had nodules in the scalp and a few small lymph nodes in the cervical region, and her spleen was palpable 6 cm below the costal margin From that time onwards the course was progressively downhill, and she died on Jan 17, 1950 without any further remission The accompanying figure shows the course of the disease

Necropsy showed gross hæmorrhage into the right internal capsule and had ruptured into the ventricular system there was considerable subtentorial clot around the pons and medulla

The interest of this case lies in the fact that aminopterin induced two dramatic complete, although temporary, remissions from both the clinical and the hæmatological aspects All bone marrow and peripheral blood films were practically normal during the short remissions, and the child appeared entirely normal clinically

TOXIC SYMPTOMS

The toxic symptoms produced by aminopterin have been similar to those reported by others, and in 13 of our patients were as follows

Stomatitis	3	Other types of rash	1
Diarrhœa	2	Epistaxis	[illegible]
Hæmorrhagic rash	3	Alopecia	[illegible]

In many instances it has been difficult to assess whether aminopterin and not the leukæmic process should be held responsible for certain of these manifestations Wide fluctuations in the number of leucocytes are often seen in acute leukæmia, it is often impossible to be certain whether, for instance, severe leucopenia or thrombocytopenia are toxic symptoms due to the aminopterin or merely features known to occur in the terminal phase of acute leukæmia Discontinuance of treatment may often be followed by remission of the toxic symptoms

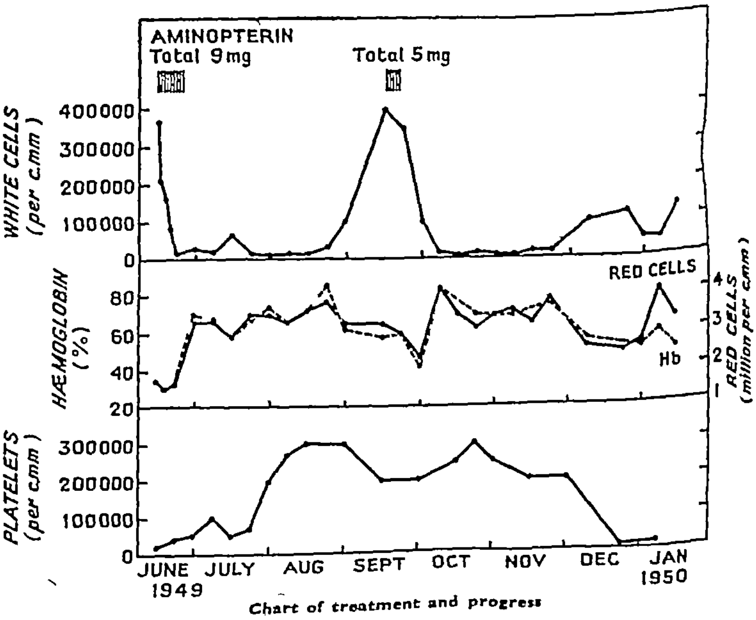

Chart of treatment and progress

DISCUSSION

The ultimate results obtained by the use of the folic acid antagonists in the treatment of acute leukæmia have so far been unsatisfactory In most patients these substances have not affected the leukæmic process to any extent, the course of the disease progressing steadily Experience has shown that the use and control of the effects of these substances is not easy, for their effects in any given case are unpredictable Toxic manifestations may be numerous, and often come on with dramatic suddenness, for the margin between the therapeutic and the toxic dosages is extremely small Consequently, the use of these substances in the treatment of acute leukæmia must be restricted, they should only be used by those fully familiar with their effects and having full hæmatological facilities for the daily control that is necessary in the beginning Nevertheless, the frequent observations that some patients show complete or almost complete, although temporary, clinical and hæmatological remissions have renewed hope for future treatment of the hitherto invariably fatal acute leukæmias It is of the greatest importance that even in a proportion (greater than the spontaneous occurrences) of acute leukæmias, many of which are certainly of different ætiology, remissions can be produced for a time by known chemical agents Quite clearly much further work is required to separate the group, or groups, of acute leukæmias that may be sensitive to this form of therapy, and to follow up the clues already appearing so as to develop more suitable and less toxic chemical substances A greater proportion of acute leukæmias do not show any beneficial response to these agents, and probably fall into other groups of different ætiology, just as the chronic leukæmias do For them other types of chemical agents are required

SUMMARY

27 patients with acute myeloid, lymphatic, or monocytic leukæmia were treated with aminopterin

6 patients received less than 3 mg of aminopterin because either the treatment had to be discontinued after development of severe leucopenia or had been instituted at a very advanced stage, the patient dying before further doses could be given

Of the remaining 21 patients, the treatment produced no response in 15, partial remissions in 4, and complete remissions in 2 for relatively short periods

One case is reported to demonstrate the ability of aminopterin to induce two dramatic complete remissions in which the clinical condition, the hæmatological picture, and the bone marrow returned to normal

We wish to thank the Medical Research Council for a research grant, the Sybil Mary Pilkington Fund Trustees for a fellowship to one of us (C G) and Messrs Lederle Laboratories Division, American Cyanamid Company, for supplying the aminopterin free both directly and through the Medical Research Council

THE DANGER OF PENICILLIN THERAPY IN GONORRHŒA

A A M REEKIE
M.B Edin
PHYSICIAN I C VENEREAL DISEASE DEPARTMENTS, PRINCE OF WALES'S HOSPITAL, LONDON, ASHFORD HOSPITAL, MIDDLESEX, AND MILLER GENERAL HOSPITAL, GREENWICH

THE treatment of gonorrhœa with penicillin has increased the risk that concomitant syphilis may go unrecognised

The incubation period of syphilis (9–90 days, average 3 weeks) being so much longer than that of gonorrhœa (12 hours–21 days or more, average 2–5 days), in simultaneous infections the gonococcal urethritis is being treated while the patient is in the incubation period of syphilis The small doses of penicillin which are so successful in curing acute gonorrhœa may suppress or modify primary or early generalised symptoms and signs of concomitant syphilis without curing it (Shafer and Zakon 1944, Camzares 1944, Hailey 1944, Ricchiuti 1944, Boyd et al 1944, Walker and Barton 1945, Kemp and Shaw 1946, Leifer and Martin 1946, Suter 1947)

The early treatment of syphilis decreases the opportunity for dissemination of infection both in the individual and in the community and appreciably increases the probability of cure (Moore 1948) Double infection is not uncommon—males 1 4%, females 3% (Kemp and Shaw 1946)—and whenever it is suspected the gonorrhœa should be treated not with penicillin but with another drug, such as sulphonamide which will not prevent syphilis from declaring itself

SIGNIFICANCE OF PYREXIA

Ricchiuti (1944), Walker and Barton (1945), Fromer et al (1946), and Leifer and Martin (1946) mention the development of chills, fever, and malaise, developing early in the course of penicillin therapy of gonorrhœa, as a possible indication of dual infection

The treatment of early syphilis with penicillin is accompanied by a Herxheimer reaction in 50–90% of cases (Moore 1949, Leifer and Martin 1946, Fromer et al 1946) The reaction is attributed to the liberation of toxins from the spirochætes either dead or in course of destruction by penicillin It is in fact therapeutic shock, and it may be systemic and/or focal It occurs with a penicillin dosage of 10 units per kg of body weight, or more, it usually appears from three to nine hours after the initial dose of penicillin and its incidence and severity are not related to dosage (above 10 µ per kg of body weight), or stage or duration of infection (Moore 1949) In early syphilis fever is almost an essential part of the reaction

Penicillin treatment of uncomplicated gonorrhœa, on the other hand, is very rarely accompanied by fever Leifer and Martin (1946) state that they have not observed fever "among hundreds of cases" Buchholtz (1946) says that, in the penicillin treatment of over 2000 patients with simple acute or chronic gonococcal urethritis unaccompanied by clinical evidence of syphilis, only 2 or 3 patients were observed to have a febrile reaction which could not be explained either by a toxic reaction to penicillin or by the coexistence of syphilis

Therefore unexplained fever and malaise during the early stage of penicillin therapy in acute gonorrhœa strongly suggest concomitant syphilis

ILLUSTRATIVE CASE RECORDS

Case 1 —A lorry-driver, aged 26 reported in February, 1948, with 4 days history of urethral discharge He had had gonorrhœa 9 months previously, treated in London Recent exposures had been 1, 4, and 8 weeks previously with different consorts no precautions had been taken at the last two The urethral discharge was diagnosed as gonococcal by smear and culture There was no clinical evidence of coexisting syphilis, blood Wassermann reaction and Kahn test were negative The patient was given one injection of procaine penicillin 150 000 units

At his next attendance, 2 days later, after inquiry, he said that about 4 hours after the injection he had felt cold and shivery and had a headache and some backache These symptoms had passed off by the next day He did not volunteer this information, because he thought that the symptoms "were due to the injection, and so he didn't take much notice of them" Clinical examination revealed no abnormality, and the urethritis was resolving satisfactorily Temperature and pulse were normal

Throughout the course of the surveillance period no further malaise occurred, and surveillance for gonorrhœa was completed in the 8th week Blood tests were negative, and there was no clinical evidence of syphilis He was instructed to continue reporting weekly, and did so In the 10th week a tiny indurated painless non tender papule was present on the dorsal aspect of the glans penis The patient was unaware of its existence The left inguinal glands were very slightly, almost insignificantly, enlarged There were no other signs suggesting syphilis Dark ground examination of serum from the papule showed *Treponema pallidum* Blood tests were still negative He denied further risks of infection since his first attendance

Case 2 — A mechanic aged 27 reported in April, 1949 with 5 days' history of urethral discharge He had had gonorrhœa 12 months previously and been treated in London Recent exposures had been 1, 4 and 9 weeks previously with different consorts soap and water had been used prophylactically after each exposure The urethral discharge was diagnosed as gonococcal by smear and culture There was no clinical evidence of coexisting syphilis, blood Wassermann reaction and Kahn test were negative The patient was given one injection of procaine penicillin 150,000 units

At his next attendance 3 days later, he said that about six hours after the injection he had a bad attack of shivering and some frontal headache, lasting until the next afternoon Clinical examination showed no abnormality, the urethritis was resolving rapidly, and temperature and pulse were normal

Surveillance for gonorrhœa continued uneventfully, and was completed in the 8th week No further malaise had occurred during this period There was no clinical evidence of syphilis and blood tests were negative The patient continued to attend weekly, and in the 11th week he said he had had a slight watery urethral discharge for 3 days, with smarting and tingling in the urethra localised to an area about 1 in from the meatus Palpation of this area revealed a small slightly tender induration A scanty serous discharge was present at the meatal orifice The right inguinal glands were very slightly enlarged and painless There were no other signs suggesting syphilis Dark ground examination of the urethral discharge showed a few specimens of *Trep pallidum* Urethroscopy showed a localised elevated erosion on the roof, 1½ in from the meatal orifice, dusky red, and exuding serum Serum obtained directly from the lesion by loop via the urethroscope showed *Trep pallidum* Blood tests were negative He denied further risks of infection since his first attendance

Case 3 —A man, aged 28, who had recently been a merchant seaman but was now working on shore, reported in August, 1949, with 3 days' history of urethral discharge He had had gonorrhœa 8 months previously (treated in New York) and 18 months previously (treated in Southampton) also 12 months previously he had had malaria, treated in Bombay Recent exposures had been 8 days (London), 5 weeks (New York), and 9 weeks (Hamburg) previously Soap and water had been used prophylactically after each exposure Homosexual exposure was denied The urethral discharge was diagnosed as gonococcal by smear and culture There was no clinical evidence of syphilis, blood Wassermann reaction and Kahn test were negative The patient was given one injection of procaine penicillin 150,000 units

At his next attendance, 2 days later, he said that 4 or 5 hours after the injection he had felt very cold and shivery, had a headache, and thought that his malaria had returned He took his temperature and found it to be 101°F He said that next day he felt much better and his temperature was normal On examination, the urethritis was subsiding satisfactorily, temperature and pulse were normal, there was no clinical abnormality, and no explanation could be given for the febrile reaction

In the 8th week surveillance for gonorrhœa was completed, there was no evidence of syphilis, the blood serology was negative, and no further malaise had occurred Surveillance was continued weekly, and in the 10th week clinical signs and blood tests were still negative Then he defaulted, to return in the 19th week with hoarseness of voice, sore throat, perineal itching and irritation, all of about 10 days' duration On examination he showed neither penile lesions nor scars nor rash, but had a very definite generalised adenitis His soft palate was deeply injected, and both tonsils were much enlarged but not ulcerated On his perineum a small cluster of flat moist indurated papules was seen at the anal mucocutaneous junction Dark ground examination of serum from a papule showed *Trep pallidum* Blood tests were strongly positive He denied further exposures since his first attendance

DISCUSSION

These cases show once more that the manifestations of syphilis can be appreciably masked by penicillin therapy for gonorrhœa This fact is common knowledge today, and in venereology due allowance is made for it Leifer and Martin (1946) found in their series that, although subcurative doses of penicillin prolonged the incubation period of syphilis, syphilis was definitely diagnosed less than 90 days after the use of penicillin In the present three cases it is impossible to pinpoint the sources of infection, but the onset of clinical signs of syphilis may well have been retarded towards the limit of the usually accepted incubation period

All three patients had a febrile reaction shortly after receiving penicillin Hence I would suggest that all patients undergoing treatment for gonococcal urethritis not only should be informed that there is a risk of concomitant syphilis being delayed in its appearance because of treatment, but also should be asked specifically whether any untoward reaction occurred shortly after receiving penicillin As in case 1, they may omit to mention this information Systemic sensitivity reactions occasionally follow injection of penicillin, but in almost all such cases there is urticaria Except for those who later proved to have syphilis I have never seen a penicillin treated patient develop fever without other signs

All patients who have had penicillin treatment for gonorrhœa should be advised to report at once the presence of any lesion, no matter how seemingly trivial, during the period of surveillance and they should be warned against sexual intercourse throughout that period They should be examined very carefully at every attendance, because very early lesions may be asymptomatic (case 1)

An unexplained febrile or other reaction a few hours after penicillin therapy should forewarn the clinician of the possibility of coexisting syphilis, and, although repeated clinical examinations may elicit no evidence blood tests in such cases should be made at least once weekly for six months after the start of treatment

SUMMARY

Unexplained fever and malaise occurring shortly after penicillin therapy for gonococcal urethritis strongly suggest coexisting syphilis, and the symptoms and signs of the oncoming syphilis may be suppressed, masked, or delayed Patients displaying such reactions should be subject to very close scrutiny, both clinical and serological, for six months from the start of treatment.

M.D Hamberg

I medizinische Abteilung, Allgemeines Krankenhaus St Georg, Hamburg

According to Shive et al (1948), Snell et al (1948), and Wright et al (1948) thymidine (desoxyribose thymine) may take the place of vitamin B_{12} as a growth promoting factor for *Lactobacillus lactis* Dorner and *L leichmannii* 313 Acting on these observations Ungley (1949) administered to a patient with pernicious anæmia 48 mg of thymidine, but it had no effect on blood regeneration Reisner (1949) also reported the ineffectiveness of thymidine therapy in doses varying from 5 to 150 mg

In two cases of addisonian pernicious anæmia I have administered a concentrate containing 85–90% of thymidine, prepared by K Mulli from the purified liver extract 'Pernical forte' The results, already briefly reported (Hausmann 1949), are here described more fully The concentrate used, according to chemical analysis, contained neither vitamin B_{12} (10 g failed to give a positive reaction with the cobalt reagent α nitroso β-naphthol) nor folic acid and thymine The small amounts of impurities present consisted of substances which in former trials had proved ineffective In quantities of 10–20 mg the thymidine concentrate exerted a growth promoting action on *L leichmannii* 313, similar to that of 1 µg of crystalline vitamin B_{12} ('Cobione,' Merck)

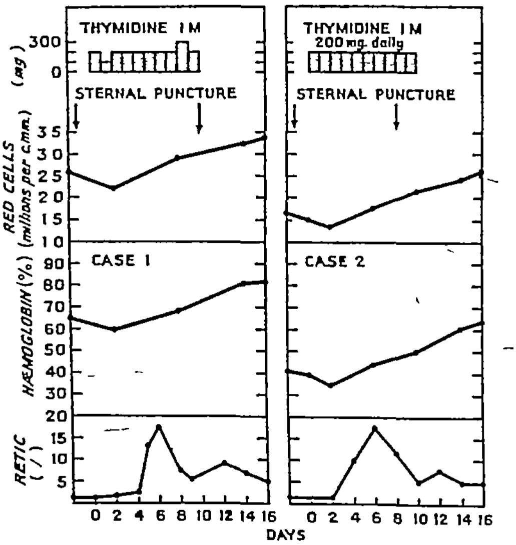

Fig 1—Quantitative changes in peripheral blood during thymidine therapy in cases 1 and 2. At the point indicated by the first arrow in each case the sternal marrow was megaloblastic, at the point indicated by the second arrow it was normoblastic.

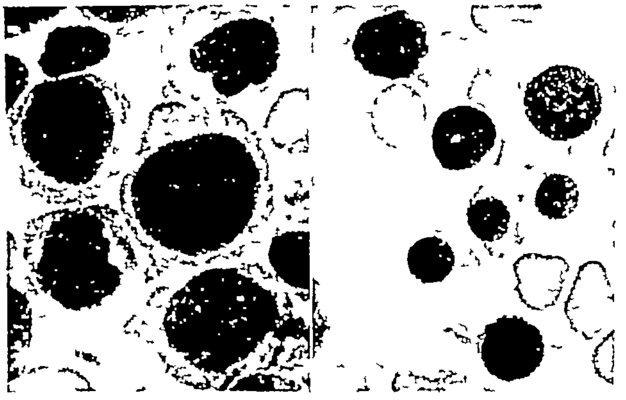
In differentiating the material obtained by sternal puncture 500 cells were counted and the count of erythroblasts, including megaloblasts, was calculated per hundred leucocytes

CASE RECORDS

Case 1—A woman, aged 54, had had liver therapy for pernicious anæmia since 1936 The last injection of liver extract had been given six months previously She was admitted to hospital because of coronary insufficiency

Examination of the blood revealed macrocytosis anisocytosis, poikilocytosis and hyperchromasia of erythrocytes, and 3200 white cells per c mm, with highly segmented neutrophils Sternal puncture showed the typical bone-marrow picture, with megaloblasts of all stages, giant metamyelocytes, and a diminished count of highly segmented megakaryocytes No free hydrochloric acid was found in the gastric juice after histamine stimulation. Anorexia, paræsthesia of the hands and feet, and general weakness were present There were no signs of glossitis or of subacute combined degeneration of the spinal cord

Treatment—Thymidine was given in an average daily dose of 200 mg (100–250 mg a day) The first injection of 200 mg was tolerated without pain but caused a slight collapse shortly after the injection The following injections had no untoward effects



(a) (b)

Fig 2—Qualitative changes in red and white cells in case 1 : (a) blood film before treatment (b) after treatment with thymidine.

Results—From the fourth day of thymidine therapy her appetite increased and weakness and paræsthesia became less On the sixteenth day there were no symptoms except angina pectoris The changes in the peripheral blood are shown in figs 1 and 2, and the bone marrow changes in the table The leucocytes reached a level of 5200 per c mm

Since no thymidine was available for further treatment, 25 µg of vitamin B_{12} ('Permipur') was administered. There was no second reticulocytosis

Case 2—A woman, aged 81 was admitted with untreated pernicious anæmia Examination of her blood revealed macrocytosis, anisocytosis, poikilocytosis, and hyperchromasia of erythrocytes with leucocytes 2300 per c.mm, and highly segmented neutrophils Her sternal marrow had the characteristic features of pernicious anæmia, with abundant megaloblasts at all stages, giant metamyelocytes, and highly segmented megakaryocytes There was no free hydrochloric acid in the gastric secretion after the administration of histamine The patient had pronounced weakness, with

STERNAL MARROW COUNTS IN CASES 1 AND 2 I WAS BEFORE TREATMENT AND II DURING TREATMENT (SEE FIG 1)

Marrow cells	Case 1		Case 2	
	I	II	I	II
Erythroid myeloid ratio	1 02 1	0 44 1	0 53 1	0 43 1
Megaloblasts per 100 white cells	78 0	0	37 5	0
Basophilic megaloblasts	20 0	0	12 5	0
Polychromatic megaloblasts	46 0	0	24 0	0
Orthochromatic megaloblasts	13 0	0	1 0	0
Erythroblasts per 100 white cells	13 5	44 0	15 0	42 5
Basophilic erythroblasts	1 0	1 0	6 5	4 5
Polychromatic erythroblasts	1 5	6 0	7 0	25 5
Orthochromatic erythroblasts	11 0	37 0	1 5	12 5
Giant forms per 100 white cells	20 0	4 5	28 0	10 0
Myeloblasts	0 5	0 5	0	0
Promyelocytes	2 0	2 0	5 0	2 5
(Giant forms)	0	0	0	0
Myelocytes	37 0	27 0	19 5	19 5
(Giant forms)	0	0	0 5	0
Metamyelocytes	22 5	10 5	19 5	18 5
(Giant forms)	17 0	2 0	13 5	5 5
Rod forms	20 0	29 5	15 0	15 0
(Giant forms)	2 5	2 0	4 5	1 5
Polymorphonuclear neutrophils	11 5	28 0	38 0	40 0
(Giant forms)	0 5	0 5	0 5	3 0
Lymphocytes	6 5	2 5	3 5	4 0

paræsthesia and anorexia but no signs of glossitis or subacute combined degeneration of the spinal cord. Some myocardial weakness.

Treatment with thymidine consisted in daily injections of 280 mg. each to a total dosage of 2·5 g. The intramuscular injections were tolerated without any untoward side-reactions.

Results.—Subjectively there was a striking improvement on the sixth day of therapy, the patient feeling much better with increased appetite and diminished paræsthesia. The rise of erythrocytes and hæmoglobin in the peripheral blood is indicated in fig. 1 and the quantitative bone-marrow changes are shown in the table. The white cells reached a level of 6800 per c.mm. After the sixteenth day of treatment the patient received 50 µg. of vitamin B_{12} (permpur), no more thymidine being available. There was no second reticulocytosis.

RESULTS AND CONCLUSIONS

The foregoing studies indicate that intramuscular thymidine 200–280 mg. (total dosage 2–2·8 g.) changed the megaloblastic marrow to normoblastic and led to a decrease of giant metamyelocytes, and in the peripheral blood produced a reticulocytosis and a subsequent increase in the red-cell and hæmoglobin count. The doses administered, however, were too small to produce a complete remission of the blood-picture. No more thymidine being obtainable we could not ascertain whether thymidine provoked nervous disturbances.

The blood-forming action of thymidine in pernicious anæmia is similar to that of corresponding doses of the various hæmopoietic active forms of vitamin B_{12} as well as folic acid and thymine. The negative results reported by Ungley (1949) and by Reisner (1949) were probably due to insufficient dosage.

In practice, the effect of thymidine in pernicious anæmia will probably be unimportant, because such large amounts of thymidine are required for blood regeneration that a depot therapy, such as is possible with vitamin B_{12} and highly purified concentrates of that substance, will be impracticable.

The value of liver extracts in pernicious anæmia cannot be ascribed to their content of thymidine, because even refined liver extracts such as pernical forte, which produce their best effects in doses of 120 mg. of solid matter, do not contain more than about 1% of thymidine.

The extreme nuclear alterations of bone-marrow cells in pernicious anæmia in relapse suggest the existence of far-reaching metabolic disturbances. As a growth-promoting factor for *L. casei* (Stokes 1944) and in the treatment of macrocytic anæmia (Spies et al. 1946) large doses of thymine, a factor in the formation of thymonucleinic acid, can be substituted for folic acid. This has led to the assumption that folic acid may function as an enzyme of nuclear metabolism. Since in tests with *L. lactis* Dorner and *L. leichmannii* 313 large doses of thymidine can be substituted for vitamin B_{12}, it may be assumed that vitamin B_{12} also exerts an enzyme influence on nuclear metabolism. The hæmopoietic effect of thymidine in pernicious anæmia supports this assumption.

SUMMARY

In two cases of pernicious anæmia a total dosage of 2 and 2·8 g. of thymidine exerted a blood-forming action comparable to that of corresponding doses of vitamin B_{12}, folic acid, or thymine.

Medical Societies

ROYAL SOCIETY OF MEDICINE

Cyclical Vomiting

THE section of pædiatrics of the Royal Society of Medicine met on Jan. 26 under the chairmanship of Dr. K. H. TALLERMAN, president of the section, to discuss Cyclical Vomiting and Allied Periodic Disorders of Childhood.

Dr. C. K. J. HAMILTON said that cyclical vomiting was first described by Gee under the name "fitful" or "recurrent" vomiting. Attacks started at the age of 3 years or less, and they usually ceased spontaneously around the age of 12. The patient was likely to be thin and nervous; often he was an only child, and commonly there was a family history of similar attacks, of travel sickness or of migraine. Attacks might be precipitated by shock, strain, excitement, infection, or dietary indiscretion, and a prodromal period of listlessness could often be recognised. After the first vomit, which might contain food taken many hours before, nothing taken by mouth could be retained, and the vomit consisted of gastric juice containing mucus, bile, and possibly blood. Associated symptoms were nausea, abdominal pain, headache, and giddiness; some of these manifestations might be more conspicuous than the vomiting, and occasionally there were convulsions. The patient might be pale and febrile and either drowsy or restless. The blood-pressure was sometimes raised and the urine contained acetone. A severe attack might end fatally, but usually recovery took place quite suddenly after two or three days.

The abdomen was lax and easy to palpate, so confusion with acute inflammatory abdominal diseases did not usually arise; but the condition was often difficult to diagnose from recurrent intestinal obstruction, intracranial tumour, and diabetic coma (glycosuria often being present). The first attack was, of course, always difficult to diagnose. Recurrent vomiting was closely connected with recurrent pyrexia without obvious cause, attacks of which might alternate with vomiting, and also with recurrent headache; but no relation with epilepsy or with allergy had been demonstrated.

Prof. STANLEY GRAHAM said that the condition could be defined as "periodic attacks of vomiting associated with marked ketosis." The attacks were sometimes called "acidosis," but this was a bad term because acidosis did not necessarily accompany the ketosis, and indeed there might be an alkalosis. In hospital attacks did not occur spontaneously, and could not be induced by giving a ketogenic diet or ammonium chloride. Professor Graham disliked the term "cyclical," because the attacks do not have any definite rhythm.

The basis of the condition seemed to be an abnormal production of ketone bodies, and possibly this represented an abnormal response by the liver to some form of stress rather than a disease entity. Turning to treatment Professor Graham emphasised the importance of treating the child as a whole; administration of extra carbohydrate between attacks was probably beneficial, but the value of fat reduction was doubtful. There was no theoretical basis for the regular administration of alkalis.

Dr. DESMOND O'NEILL spoke on the psychiatric aspect of abdominal pain. He described a study made at Guy's Hospital by Dr. R. C. Mac Keith and himself on a consecutive series of children attending the outpatient pædiatric clinic with recurrent abdominal pain as a presenting symptom, for which no physical cause could be found. In several of these children vomiting occurred in some of the attacks. The purpose of this study was to determine whether the abdominal pain could be regarded as an adaptive disorder—that is, whether it was related to emotional tension from maladaptation to stresses which the child had to meet. It was found that emotional tension was, in fact, the principal determinant of the pain in 15 out of 25 children, and that it was a contributory factor in another 6. Of this group of 21, 17 had other tension signs, such as headache, poor sleep, tics, and behaviour disorders. In 11 there was a history of nervous disturbance or stress disorder in one or both parents.

Anxiety and fear were much the most common emotional states associated with pain, fear of the teacher at school or of being bullied was often found. Once the attacks had been set in motion in this way, a complaint of abdominal pain might be made in order consciously or unconsciously, to escape from an unpleasant situation. The effect of simple psychotherapy, in which play therapy had an important part, was striking reduction or disappearance of the pain being achieved in a high proportion of cases. In some children under treatment the pain was replaced by another symptom, such as screaming attacks, and this had in turn to be treated.

Dr R E **SMITH**, whose paper was read in his absence by Dr D V Hubble, dealt with the prognosis and sequelæ of recurrent vomiting, basing his conclusions on a study of 700 boys between the ages of 13 and 18 at Rugby School. Of those who had had attacks in childhood nearly a quarter continued to do so in adolescence, but there was a well-marked decline around 15–16 years of age. Acute appendicitis might be overlooked in a boy subject to these attacks, but otherwise they were not serious.

Dr **HUBBLE** also described the findings in a fatal case of his own, in which there was hypertrophy of the pylorus. He suggested that during life there might have been pylorospasm and reversed peristalsis, and he thought that a similar mechanism might account for the vomiting of migraine. He had found ergotomine tartrate of value in recurrent vomiting as well as in migraine.

Dr R C **MAC KEITH** remarked on the interval of up to 48 hours that often elapsed between the exciting cause and the onset of the attack.

Dr J P M **TIZARD** referred to some organic causes of recurrent vomiting, such as tonsillitis, pyelitis, œsophageal stenosis, and intestinal obstruction, and Dr H. R **JOLLY** mentioned lead poisoning.

Dr J J **KEMPTON** observed that the subjects of recurrent vomiting are often in a state of mild chronic ill health, correction of which suffices to bring about improvement.

Prof A. A. **MONCRIEFF** emphasised the importance of adequate rest for these children, and the value in many cases, of a regular sedative. The infections precipitating attacks might be very slight, and detectable only by careful examination. Professor Moncrieff also spoke of the need for a control series in evaluating the rôle of emotional factors in causing symptoms.

Dr W W **PAYNE** said that in the subjects of recurrent vomiting the glucose tolerance was normal between attacks, but there was some delay in the storage of lævulose. He had often found the blood sugar raised at the beginning of attacks. He had noticed that in diabetic children hypoglycæmia was often accompanied by abdominal pain, vomiting, and diarrhœa, which were presumably due to overaction of adrenaline. He wondered whether recurrent attacks of vomiting might be precipitated by a similar mechanism followed by exhaustion of the glycogen reserve of the liver and hypoglycæmia and a further excessive adrenaline action. Dr Payne therefore recommended repeated administration of carbohydrate during the day between attacks and a sedative to reduce sympathetic overaction.

Dr G M **KERR** said that in practice the best description to use was still ' bilious attacks ', he thought that these cases were as numerous as ever, but that fewer were being referred to hospital. The patient might be given a rectal sedative if nothing could be retained by mouth.

The **PRESIDENT** pointed out that in organic abdominal disease the pain was likely to be more severe, and not so commonly associated with headache and pyrexia. He thought " abdominal migraine ' a good descriptive title for these attacks.

Mr J T **EDWARDS** described acetonæmia " in cows, and recurrent vomiting in puppies. Highly selected strains were most liable, and they were also unduly nervous and relatively infertile. Replying to the discussion, Professor **GRAHAM** said that he had found the blood-sugar to be normal between attacks. He had also seen asthma arise as a sequel, and he believed this to be commoner than migraine.

Reviews of Books

Peptic Ulcer

A C IVY, M D, vice president of the University of Illinois, M I GROSSMAN, M.D, associate professor of physiology, University of Illinois, W H BACHRACH, M D, research associate in physiology, University of South Carolina School of Medicine. London J & A Churchill 1950 Pp 1144 96s

HERE is the accumulated experience of many physicians surgeons, physiologists, and pathologists. Indeed Dr Ivy and his collaborators seem to have gathered together almost all our current knowledge of peptic ulcer. In performing this monumental task, they have summarised clearly the great mass of often contradictory evidence, and present reasoned conclusions. The result is a valuable and important book. Of the four major parts that on pathogenesis is by far the largest. Diagnosis gets relatively scant attention—a bare 100 pages—while treatment rightly has double as much. The section on pathogenesis covers modern work on experimental production of ulcer constitutional and environmental factors, and the role of the nervous system, and there is a good discussion on psychosomatic—or as the authors prefer to call them " emotogenic "—causes. There are innumerable references, and many excellent illustrations and diagrams.

This is the magnum opus of an outstanding gastroenterologist. All interested in peptic ulcer will feel indebted to Dr Ivy.

Surgery of the Eye Injuries

ALSTON CALLAHAN, M D, F.A.C S, professor of ophthalmology, Medical College of Alabama, director, Thigpen Cater Eye Hospital, Birmingham, Alabama. Springfield, Ill Charles C Thomas. Oxford Blackwell Scientific Publications 1950 Pp 217 84s

THE experience which led Professor Callahan to write this book was gained when he was surgeon to an army ophthalmic centre, and afterwards to a civilian eye hospital. As he says in the introduction the work is not an all-encompassing text of eye surgery, but is concerned only with the repair of injuries and of the deformities they produce. No part of the eye or adnexa is omitted and he begins with corneal suture and ends with repair of the bony walls of the orbit, but it seems that his chief interest relates to structures outside the globe of the eye. Corneal grafting, for instance, is treated with extreme conservatism as being rather dangerous, and three-quarters of the text deals with the injuries to the adnexa. Nevertheless, his presentation of the methods employed in a variety of injuries is outstandingly successful, actual cases being beautifully illustrated and lucidly described. Moreover, this is a delightful book to read and handle.

Osteology for Dissectors

A Tutorial Pocketbook. ROBERT KING HOWAT, M.B, F.R C.S, F.R F.P S, hon demonstrator of anatomy King's College London. London Henry Kimpton 1950 Pp 292 15s

ONE of the objects of this book is to promote the study of the bones and soft tissues as an interdependent whole, each component of which explains the other. Mr Howat therefore places considerable emphasis on living and functional anatomy. Indeed, several short notes are included on subjects not strictly to be classified as osteology, such as the mechanics of respiration, the muscles of the back, and the muscles of facial expression.

In the descriptions of the bones the main features are clearly and succinctly brought out, but minutiæ are left out the vexed subject of ossification dates is sensibly treated by the omission of detail. The book is illustrated by 46 rough outline drawings on which the student is expected to sketch in the various muscular and ligamentous attachments.

The text is essentially in the form of notes and the arrangement of material is occasionally odd. For example though an introductory section is given the various types of epiphyses are not classified until p 131, where the classification is somewhat arbitrarily introduced into the description of the femur. Nor is the treatment of the skull bones wholly logical the palatine bone is described in the text, but the ethmoid is relegated to an appendix. The list of contents leads one to expect a separate description of the sphenoid, but none is given, nor does the sphenoid appear in the index. The index is, indeed, inadequate and often capricious. The terminology used is deliberately inconsistent, which may serve to accustom the student to the conditions he will encounter later in the curriculum, but which may also, at this early stage, confuse him. Nevertheless, the book may prove of value to those who find the larger osteology texts too detailed and too far divorced from the study of the anatomy of the soft parts.

The National Health Service Acts, 1946 & 1949

J. A. SCOTT, O.B.E., M.D., D.P.H., deputy medical officer of health, London County Council; D. J. B. COOPER, A.C.I.S., principal clerk, L.C.C. public health department; S. SLUFFERT, of the Middle Temple and the South-eastern circuit, barrister-at-law. London: Eyre & Spottiswoode. 1950. Pp. 1192. 55s.

IN 1947 Dr Scott published a slender volume called *The National Health Service Act, 1946*, containing an informative introductory chapter, the text of the Act, and an index to the Act compiled by Mr H. A. C. Sturgis. In this new version, which bears about the same relative proportions to its forerunner as Falstaff to his page, Dr Scott has had the help of Mr Cooper and Mr Scuffert. The introduction has been largely retained and expanded, and a chapter has been added on the scope and structure of the National Health Service, informative and easy to follow. The texts are given of the 1946 Act, the 1949 (Amendment) Act, and the Statutory Instruments Rules *and Orders (as amended)* issued up to March 31, 1950; both Acts are fully annotated in a manner which relates allied subjects, fills in gaps, and throws a beam through the haze of official language. Appendices include a pictorial diagram of the administrative structure of the service, the statutory rules and orders relating to regional hospital areas, a list of disclaimed hospitals, an account of the prospect of health centres, the text of Ministry of Health circulars of "particular interest and importance," and a list of Whitley Councils; and there is a comprehensive index. Professional and amateur administrators who found the original volume a useful acquaintance will be quick to make friends with its larger successor.

Asphyxia Neonatorum

WILLIAM F. WINDLE, PH.D., professor of anatomy, University of Pennsylvania. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1950. Pp. 61. 15s.

THIS monograph in the series "American Lectures in Physiology" represents "the revised text of several lectures in an elective course in 'Developmental Physiology' at the University of Pennsylvania." It is concerned with the relation of asphyxia neonatorum to the fœtal blood, the fœtal circulation and respiration, and the effect of this condition upon the brain.

The subject is introduced with a discussion of fœtal-maternal relationships, and thereafter the blood of the fœtus and of the newborn is considered from the aspects of development, disposition, volume, and iron content. Other chapters are devoted to fœtal circulation, intra-uterine respiration, fœtal respiratory activity, and the advent of air breathing. Only the last chapter deals with asphyxia neonatorum as such, from experimental and pathological points of view.

Professor Windle is not one to accept statements without putting them to the test of experimental proof, as the following quotation illustrates: "Some are content to assume that a significant percentage of the population is born defective mentally and that this defect may be the cause rather than the effect of respiratory abnormality at birth. Although clinical evidence suggests a close relationship between asphyxia at birth and late neurological defects in infants and children, adequately controlled experimental conditions are practically non-existent in the human species. Consequently, it is essential to turn to the laboratory and try to reproduce similar conditions in animals that give birth to two or more offspring."

This is a notable monograph on a subject of increasing importance to obstetricians, pædiatricians, physiologists, and pathologists.

British Encyclopædia of Medical Practice (2nd ed. London: Butterworth Medical Publications. 1950. Vol. 4. Pp. 688. £3).—The fourth volume of this standard work in its second edition, edited by Lord Horder, goes forward alphabetically from corneal lesions (reviewed by Mr J. H. Doggart) to ear diseases (by Mr Maxwell Ellis). Technically this volume is noteworthy for fine colour illustrations of the tympanic membrane.

Annual Review of Medicine (Stanford University School of Medicine, California: Annual Reviews. 1950. Pp. 454. $6).—Essentially intended for those engaged in teaching or research, volumes in the "Annual Reviews" series are designed to cover all the principal advances in knowledge in their special subjects. The present volume, edited by Windsor C. Cutting and Henry W. Newman and carrying an imposing list of authors, is remarkably up to date. Besides quoting from large numbers of original papers, the various authors give their own views clearly, and keep a good balance between experimental and therapeutic results. Some 250 reviews on medicine published between July, 1948, and November, 1949, are annotated, and the authors referred to amount to nearly 4000.

Atlas d'Électrocardiographie (2nd ed. Paris: Masson. 1950. Pp. 260. Fr. 2200).—This atlas, intended for beginners and for practitioners, is compiled by V. Fattorusso and O. Ritter, and is based on very clear tracings, which—though evidently retouched—are faithful reproductions of the originals, many of which were taken in the clinic of Dr F. N. Wilson at Ann Arbor. In subjects which have recently advanced, particularly cardiac infarction, the book is up to date, and wherever possible an electrical anatomical explanation is given for the tracings. For those who wish to go a little deeper into the matter there is a supplementary section on electrophysiology, with brief notes on vectorcardiography and on the ventricular gradient. The atlas can be recommended to anyone with a little French; but the price is high for a book with soft paper covers.

Foot Mechanics (London: Baillière, Tindall & Cox. 1950. Pp. 106. 6s.).—Leslie R. Smart, chiropodist to the Bermondsey and Southwark group of hospitals, sets out to describe the mechanics of the foot and the principles of *treatment of mechanical disorders, and to correlate chiropodial* measures with other methods of physical treatment. His account of the mechanics and functions of the foot and of its common disorders is clear and straightforward, though more emphasis might have been laid on the functional importance of the toes. In the chapters dealing with methods of diagnosis and treatment it is disappointing to find that emphasis is laid on technique rather than principles. Thus the operative treatment of hallux rigidus is described in detail, but the indications for operation, and the results that may be expected, are not mentioned. In a book of this kind it is surely unnecessary to discuss the technique of giving local anæsthesia, or the development of an X-ray plate: space would be far better given to a fuller account of the indications for the forms of treatment advocated.

A Medical Handbook for Athletic and Football Club Trainers (London: Faber & Faber. 1950. Pp. 144. 10*s.* 6*d.*).—A certain amount of scientific and medical knowledge is desirable and indeed necessary for a correct understanding of the training of footballers and those engaged in other athletic ventures. But it is far from easy to define the limits of such instruction, and in this book Mr W. D. *Jarvis has attempted too much in some directions* and too little in others. He clearly has a good superficial knowledge of anatomy and physiology; but a profound knowledge of these is required by anyone setting out to impart elementary principles to beginners, and to preserve a proper proportion in selection of material. Is an athletic trainer any more efficient because he knows about the cytology of the blood, the character of the heart sounds, the gaseous changes which influence the respiratory centre, the structure of the intestinal wall, the anatomy of the brain and of the autonomic nervous system, and the anatomy and physiology of the endocrines? The details of first aid are sound, but references to the differential diagnosis of such diseases as peritonitis are out of place. A man with considerable practical experience of athletes must have many more useful things to offer than an epitome of current textbooks for the medical student.

LANCET

TURDAY, FEB 10, 1951

er Cookery

T[illegible] Working Party[1] makes two mai[illegible] [illegible]endations (1) that premises used in the [illegible] should be registered with local authorities and (2) that a "standard" code of hygienic practice should be enforced In addition it has drawn up a 'target' code at which catering establishments, great and small, are advised to aim. Not all the members of the working party could agree that a local authority should have power to prevent the proposed use of premises on the ground that the plans and plant are going to prove unsatisfactory, and members representing the trade raised the reasonable objection that the major dangers to public health arise not from failings in layout or equipment but from the dirty habits or lapses of the workers We too are not over-fond of provisions—necessary though they be at times—which leave a citizen's livelihood to the discretion of the single expert employed by a statutory body

The dangers to the public from the catering trade are those of food-poisoning in its many forms Food may be dangerous when it reaches the restaurant, or while on the premises it may be rendered dangerous by human or animal contamination or by the multiplication of bacteria derived from these or other sources At any stage, and sometimes by almost grotesque ill chance, it may adsorb metallic and other chemical poisons The measures proposed in the "standard" code to lessen these dangers are those suggested by reason and experience Working premises must be kept clean in every sense, and vessels and equipment should be what the good housewife calls spotless Lighting and supplies of hot and cold water must suffice for every purpose Perishable food must be kept at a temperature below that at which bacteria multiply freely, and viands to be eaten cold must, after cooking, be chilled as rapidly as possible Interpreted with caution, regulations such as these could be enforced Whether this is true of those directed against infection derived from the people who handle food we are less certain The working party rightly rejects the proposal so often made, that all employees should submit to medical inspection at regular intervals or at least on engagement Even if such an inspection were limited to a search for carriers of enteric fever, such as is undertaken before men are employed in waterworks the time and money spent to no advantage would soon bring the system into disrepute Enteric fever is mercifully rare, while food-poisoning caused by salmonella shigella and staphylococcus is only too common Cumulative experience suggests that, though a permanent carrier may occasionally be responsible for these infections, the commonest source is the person with a superficial infected wound of hand or face or with a discharging nose or one who returns to work free of symptoms after a bout of diarrhœa, or who is the unwitting family contact of an infected person[2] We should not care for the task of framing regulations adequate to control these sources of infection, and we doubt whether this "standard" code will be of much help in this direction Indeed the results of applying this code as a whole will deserve close attention from those interested in the science (or art) of citizenship So long as social regulation was limited to the obvious externals of our living, enforcement was not difficult The Elizabethan cit who did not attend his church on Sunday or the wretch who failed to obscure his house lights in the blackout, were sitting birds to the legal gun But the kitchen-hand who fails to report to the restaurateur that he passed a fluid motion during the night (Standard Code Sect 2b) will be elusive game It is fair to ask whether expert knowledge is not, with the best of intentions, pushing us too deep into the brier-bush of unenforceable regulations If these were based on facts beyond dispute we should feel less uneasy but if this working party had met in 1940 its findings would not be what they are now, and its successor in 1960 may not accept its premises and suggestions unamended

But, if some misgivings are permissible, no-one should make light of this report for, applied with sense and tact, its suggestions will do much to enhance the safety of those who eat in public and those who buy cooked food People who cynically deny the possibility of improvement in these matters would do well to consider the ice-cream trade, where a single regulation demanding pasteurisation a practical but non-statutory test of bacterial contamination, and the wholehearted support of the makers, have together entirely changed the quality of the article sold to the public Today food hygiene is headline news, and to make this report effective some responsibility lies with the popular expositors of hygienic living A public which grumbles with intelligence is unlikely to come to much harm. and the critical diner-out will send the dirty plate back quicker than a ream of regulations Perhaps, too the sanitary inspector will learn to look more often at the waitress's finger-nails and less severely at the height of the kitchen ceiling And every doctor will help if he notifies to the M.O.H. any outbreak of gastro-enteritis involving two or more persons

Methods of Rat Destruction

THE war stimulated study of scientific methods of destroying rats In Britain the centre of investigation was the Bureau of Animal Population at Oxford and some of the work done there has been reviewed by BARNETT[3] Poisoning remains the method of choice but difficulties arise from the tendency of rats to avoid anything unfamiliar ("new object reaction") which leads to refusal of poison when first put down.[4] After an interval of hours or days small and often sublethal quantities are taken, and a rat which recovers from poisoning may afterwards refuse the food that caused his illness ('bait-shyness') In the now familiar technique of "prebaiting" plain bait is laid for several days before poison is added, and the rats thus become accustomed to the new food THOMPSON[5] has shown that if the amount of bait laid each day is much less than the rats need, feeding becomes more and more concentrated into a short period immediately after the bait is put down, and when poison is eventually added the mixture is taken readily in lethal amounts Prebaiting, however, is laborious, and it is hard for organisations such as local health departments to find the labour for it Moreover, even prebaiting may leave some survivors, and these, according to official advice,[6] should be dealt with by a further course of prebaiting and poisoning, with different materials to avoid possible shyness If this is not done, or if for any reason complete or nearly complete clearance is not achieved, the rat population may restore itself rapidly by breeding

[4] Chitty D., Shorten M. J Mammal 1946 27 63

For economic reasons, therefore, a means of doing without prebaiting is needed, and BARNETT and his colleagues have investigated this problem One possibility is a poison so toxic that rats could rarely, if ever, take a less than lethal dose, and it has been widely suggested that sodium monofluoroacetate ("1080") meets this need Of 16 carefully assessed field tests of 1080, used without prebaiting, 10 were judged successful, 4 were failures, and 2 were doubtful[7] 1080 is therefore considered better than the commonly used rat poisons (such as zinc phosphide) without prebaiting, though the results are not as reliable as those of the normal prebaiting procedure But 1080 is very dangerous, and a number of domestic animals and wild birds were killed during the tests Also it was found that rats surviving 1080 poisoning may refuse further baits containing the poison Since the LD50 of 1080 to wild *Rattus norvegicus* is 4 mg per kg or less, this is of considerable interest it shows that an increase in toxicity which would obviate prebaiting must be so great that it is probably impracticable The problem would be solved if a highly toxic, palatable poison could be found, *specific to rats*, but only one substance is known to be fairly specific to rats—namely, scilliroside, the toxic glucoside of red squill—and this poison has proved ineffective without prebaiting[8]

An alternative way to make prebaiting unnecessary would be to use a poison that did not cause shyness Such a poison could be laid continuously, in infested places, without loss of efficacy ARMOUR and BARNETT have tried the anticoagulant dicoumarol in an investigation of this possibility, which they call "chronic baiting"[9] As dicoumarol acts slowly, and has little effect after a single dose, it was thought that the rats would not learn to avoid it But laboratory and field tests, all on wild rats, showed that dicoumarol is capable of producing shyness, though to a less extent than strong poisons, and also that it is distasteful to rats Granted, however, that dicoumarol is not the ideal substance for chronic baiting, the fact remains that ARMOUR and BARNETT found that in the field it gave kills of over 70% in 6–9 weeks, laying bait only once a week And SCHEIN[10] reports briefly even higher kills in some environments with another anticoagulant, Compound 42 or 'Warfarin' Though a great deal more work needs to be done, it seems likely that chronic baiting with special poisons will be the next stage in the development of methods of rat destruction

Contaminants in the Blood-culture

COAGULASE-NEGATIVE strains of *Staphylococcus albus* are almost always harmless saprophytes, and when found in a blood culture they are therefore reported as contaminants But in the two cases reported by Dr MATTHEW three weeks ago (Jan. 20, p 146) there seemed to be no doubt that they were the cause of a fatal infective endocarditis Diphtheroids, bacilli resembling *H influenzæ*, and enterococci, as well as these white staphylococci, have on rare occasions grafted themselves on damaged heart valves and instituted an infection which in pre penicillin days was almost invariably fatal These cases usually have a persistent pyrexia, probably related to the continuous release of bacterial protein—an accepted pyrogen—into the blood stream, and the breaking off of friable endocardial vegetations causes the non septic infarcts often found in various organs Myocardial infarction is a rarity, but it was a feature of MATTHEW's cases, where it led to a secondary pericarditis with effusion. In cases of bacterial, but not rheumatic, endocarditis this complication of pericardial effusion should make the clinician consider the possibility of infection with *Staph albus*, even though the reports on blood cultures have hitherto mentioned it *only* as a contaminant

Despite this evidence of its very occasional pathogenicity, *Staph albus* remains the commonest contaminant found in blood cultures taken by inexperienced housemen, where it may be derived from the patient's skin, the operator's hands, or the environment Students nowadays are often called upon to draw blood for various purposes, and they should be taught the correct technique of venepuncture early in their clinical training A short technical film, on the lines of *Taking a Blood-culture*, which was shown to the Royal Society of Medicine at St Mary's Hospital in November, would tell them how the risk of introducing contaminants can be reduced to a minimum The important points are to use a syringe *ready assembled with a sharp needle* and sterilised by dry heat, to have the patient's arm fully extended on a resistant surface, and to feel as well as see the vein chosen for puncture (avoiding the shifting superficial kind) A sphygmomanometer cuff having been applied to the upper arm and inflated just enough to make the veins stand out, the skin is painted with 2% iodine or 70% alcohol, and the operator then introduces the needle as nearly as possible parallel to the vein, *to avoid catching the opposite wall* The blood should flow into the syringe without undue suction by the piston, and without including any air bubbles After its withdrawal from the vein the needle is left attached to the syringe and the blood is slowly ejected into the appropriate culture media—bottles or tubes with screw cap and rubber diaphragm enable one to inoculate the medium without exposing it to the outside air

Besides the usual aerobic and anaerobic culture (and, where undulant fever is suspected, incubation in 5–10% CO_2), an attempt at a quantitative culture an be made if, when the blood is being collected, wo 1 ml amounts of blood are added to tubes of nelted agar which are then emptied into petri plates f this is done routinely in cases of obscure pyrexia, t will be possible for the laboratory to say whether ny dubious organism is a pathogen, for contaminant rganisms will usually number less than 1 and patho gens more than 1 per ml It will also help to differ ntiate a temporary bacteræmia, with, as a rule, less han 10 organisms per ml, from a true septicæmia, where—for example, in subacute bacterial endocarditis —the number per ml may range from tens to undreds

Annotations

INFLUENZAL PNEUMONIA

EXCEPT for rare cases which radiologically belong to the "atypical pneumonia" group of infections, influenzal pneumonia seems to be caused by pneumococci, staphylo cocci, streptococci, or *Hæmophilus influenzæ* We may think of these bacteria as opportunists exploiting gaps in the defences, consolidating in areas whose perimeter has been weakened by influenza virus The incidence of pneumonia differs greatly in different influenza outbreaks and even in different areas where the same strain of virus seems to be at work Many experienced bacteriologists believe that *H influenzæ* was of special importance in the 1918 pandemic of virus influenza, and there is some evidence that particular bacterial species tend to predominate in particular outbreaks The relationship of bacteria and virus is thus very important in considering influenzal pneumonia Bacteria play the main part in the later stages but both virus and bacteria have frequently been isolated in the same case Finland et al.[1] found that half of 69 cases of bacterial and other pneumonias gave positive serological tests for the virus Maxwell et al.[2] obtained serological evidence of infection or isolated the virus in 17 of 36 cases of pneumococcal pneumonia Now Stuart-Harris and his colleagues[3] in Sheffield report that at least 18 of 55 cases of pneumonia during the spring of 1949 were infected with influenza A virus In addition, 8 of 15 cases of bronchitis, 1 of 2 cases of bronchiectasis, and 4 of 6 cases of congestive heart failure also had evidence of virus A infection These positive results were confined to the period of prevalence of influenza A, and only 2 out of 158 patients, including 78 cases of bacterial pneumonia, were infected with the virus when there was no epidemic. The Sheffield workers isolated *Staphylococcus aureus* from several of their cases of influenzal pneumonia, particularly from the fatal ones and this type of infection should be constantly kept in mind

One of the striking features of certain cases of influenzal pneumonia associated with *Staph aureus* is the ease with which influenza virus may be recovered from the lungs of fatal cases Some workers believe that this indicates a special relation between the virus and the bacteria, but the rapidity with which staphylococcal pneumonia develops may also be relevant On the other hand, there may be some sort of synergism at work, and possibly a staphylococcal spreading factor plays a part From the clinical angle, synchronous virus and staphylococcal infection is particularly important because it may resist many forms of current treatment In influenzal pneumonia associated with pneumococci there is less evidence of synergism, and in such cases the clinical features and the response to treatment do not differ materially from sporadic cases of pneumococcal pneumonia Harford et al[4] showed that the power of the mouse lung to reduce its content of pneumococci was less in the presence of influenza virus infection, but in these experiments definite lung lesions were produced by the virus itself We cannot, therefore, lightly dismiss the possibility of some sort of concerted attack between virus and bacteria especially where the influenza and pneumonia infections are not separated by an appreciable interval of time

Another form of relation between the virus and bacterial agents in influenzal pneumonia is suggested by the Sheffield workers Certain organisms present in the nasopharynx as peaceful residents may be transferred and "passaged" from one person to another along with the virus. It is possible that during this transfer an epidemic strain of the bacterium might emerge, and, if this happened, more cases of pneumonia associated with this virulent strain would occur than before the outbreak, and these infections might be combined with influenza virus infection No single serological type of pneumo coccus was particularly common among the Sheffield cases, but other workers have found a prevalence of one type in other outbreaks There is a suggestion that one bacteriophage type of *Staph aureus* was common in Sheffield during the epidemic, but this may not mean very much The investigation does not shed much new light on the virus-bacteria relationship in influenzal pneumonia, but it is a valuable record of what happens in a community when, as at present, influenza virus reaches it from abroad

THE WORK OF THE BORSTALS

A Home Office pamphlet, Prisons and Borstals,[5] reminds us that in 1863 a committee of the House of Lords reported in favour of a punitive regime in prisons, based on "hard labour, hard fare, and a hard bed" This was interpreted as requiring complete isolation of the prisoner at all times, and his employment on irksome, fatiguing, and useless labour at the treadmill, the shot-drill, and the crank In 1895 a departmental committee, with Lord Gladstone as its chairman, found that under this system neither crime nor recidivism had decreased, and that prisoners, far from being deterred, became degraded, embittered, and confirmed in their choice of a criminal life The committee recommended that, in future, reformation and deterrence should go hand in hand, and that "prison treatment should be effectually designed to maintain, stimulate, or awaken the higher susceptibilities of prisoners and turn them out of prison better men and women, both physically and morally, than when they came in"

Nowhere in the prison service has the attempt to apply these principles been more earnest than in the borstals, and achievement has been considerable, though it is partly limited by lack of appropriate staff and buildings There are two reception centres for boys, one at Latchmere House, Kingston, and the other in a wing of Wormwood Scrubs Prison Until recently girls were received at Holloway Prison but now they are sent directly to the borstal at Aylesbury The Howard League[6] think the continued use of a prison as a reception centre is unfortunate and so indeed do the Prison Commissioners Boys are studied for about two months at the reception centres, and are examined medically, educationally, and psychologically A woman social worker visits the home and reports on the family background of each young offender, and finally he is assessed for vocational training On the basis of these studies he is allocated to the borstal most likely to suit him Of the 13 institutions available 4 are in 'security" buildings, 7 are in camps or adapted country houses, 1 is a specially built open borstal, and 1 is in an old prison with an outlying camp , there are also a correctional borstal for absconders in a wing of Wandsworth Prison, and a recall centre at Portsmouth for the further training of those recalled from supervision Girls under borstal training are far fewer than boys (an average of 275 against 3100 in 1949), and less choice of training is open for them There are only two centres—that at Aylesbury (a "security" institution with a farm outside the walls), and an open borstal at East Sutton, where 40–50 suitable girls are trained in an adapted country house

[6] Borstal a Critical Survey London Howard League for Penal Reform. 1950 Pp 43 2s 6d

A statutory duty is laid on the borstals to provide continued education for the inmates, not only by class teaching but by means of hobbies and handicrafts , and in addition eight hours every day are spent at work, at first in construction and maintenance about the house and farm and later in training for a trade The boys are taught by self respecting craftsmen, vigorous and often athletic, who provide, as the Howard League survey says, a living proof that honesty is not a sign of effeminacy and weakness Small sums can be earned at work, which can be spent in the canteen For the girls there is much less choice of occupation then for the boys , until recently domestic work and sewing were the only resources offered to young women who before admission had mostly been living lives of considerable excitement Nowadays, however, they have opportunities to learn dairy farming , and at East Sutton they also help with building and maintenance, and not surprisingly many of them show much aptitude for these things The Home Office pamphlet notes that the spare time activities at borstals are valuable instruments of training A library (often a branch of the county library system), indoor and outdoor games, matches played against neighbouring teams, cadet corps, boys' clubs, young farmers' clubs, summer camps and harvesting camps, and the oppor tunity to go home for five days' leave, all bring these young people into touch with the community, and help them to know they have a place in it

The aim of all borstal training, as the Howard League point out, is to fit the young offender for ordinary life by giving him increasing responsibility, both in his environment and for his own self discipline The duration of a borstal sentence is, in effect, for four years, of which not less than nine months and not more than three years must be spent in the institution, the rest being a period of supervised freedom How far is the system successful ? It is generally reckoned that the approved schools are successful with over three quarters of their cases , the borstals, faced for the main part with the tougher delinquents, succeed with more than half Thus of boys discharged in the years 1942–46, 52 1% had not been reconvicted up to 1948, and 22 3% had been reconvicted once only For girls the figures were 59% not reconvicted and 21 9% reconvicted once only But about a quarter of the boys and a fifth of the girls had been reconvicted more than once in that time , and for these we must take yet more thought Among constructive measures the Howard League propose that staff should be increased by offering higher salaries, and by experimenting in the use of more women staff in the boys' institutions Special institutions should be provided, they suggest, for absconders from approved schools (especially for those children who have been sent to such schools because they needed care and protection), for children of very low intelligence, and for psychopaths No part of a borstal sentence, they think, should be served in a prison building The welfare of those who leave is now in the hands of a Central Council for Aftercare The Howard League feel that such care might well be more personal and less formal more use should be made of voluntary workers, and there should be one or more officers in every borstal to act as a liaison officer for aftercare Better aftercare, indeed, might make all the difference to some, for a boy who leaves with the knowledge that he is well on the way to becoming a skilled workman may find his way blocked by trade union regulations when he tries to get a job , and his bitterness may lead him back to crime

We have good reason to be proud of the work done by our approved schools and borstals With more staff they could probably diminish still further the residue of young people who still sink into the miserable career of the persistent offender

SEASONAL INCIDENCE OF POLIOMYELITIS

In the tropics the incidence of poliomyelitis does not vary with the seasons, but as one moves north or south of the Equator there is an increasing tendency for outbreaks to occur in the warm months of the year Exceptional seasonal outbreaks are not rare but generally speaking the rule holds The explanation which comes most readily to mind is that climate affects the means of transmission of the virus, whether we believe this to be by droplets or by food and drink If the disease is spread by contact we must explain why outbreaks occur when people are spending most time in the open air, and Armstrong[1] meets this paradox by suggesting that the portal of entry of the virus is more permeable in warm weather When it is cold the secretions of the nose and throat, which are thought to have a protective effect, are greatly increased Mucous secretion at its site of penetration may dilute or carry the virus away and at the same time make it more difficult for the virus to come into contact with susceptible cells in the nasopharynx In warm weather, when secretions are less, the opportunities for virus penetration will be better, and Armstrong has shown that there is a striking correlation between the absolute humidity, the average monthly temperature, and the incidence of poliomyelitis in the United States Similarly, in our public health section (p 355) Dr Ian Taylor's chart illustrates how London epidemics in the last few years have begun as soon as the average temperature at Kew reached 60°F But if this correlation means anything, why do mumps, influenza, and chickenpox not flourish in the same sort of weather ? The difference may be concerned with the type of cell which attracts these viruses

In search of experimental support for his hypothesis, Armstrong suspended the Lansing strain of poliomyelitis virus in varying amounts of mucin, and after centrifuging injected the supernatant fluid intracerebrally into mice Mucin appeared to snare the particles of both poliomyelitis and herpes simplex virus, since the tubes containing the highest concentrations of mucin were least infectious Next he injected mice intracerebrally with herpes virus suspended in mucin and 4 out of 30 survived whereas all 43 controls died A similar protective effect was noted when the injections were given into the pad of the foot or into the loose tissues of the groin Using a strain of rabies virus he found that 5 out of 12 mice survived when mucin was added to the intracerebral inoculum whereas all 12 control mice died. In all of these experiments mucin delayed the infection, and although only a proportion of the animals survived the results might have been better if as in the nasopharynx, there had been a continuous supply of fresh mucin The effect of this substance in the virus experiments is exactly the reverse of what happens in some experimental bacterial infections where mucin enables a feebly pathogenic organism to initiate infection In those infections mucin protects the bacteria from the host's defences , here it forms a protective barrier between virus and the susceptible tissue cell If the seasonal incidence of poliomyelitis is related to the conditions of the portal of entry or exit for the virus it is conceivable that such conditions could be altered by artificial measures Armstrong's hypothesis may not be entirely convincing but it suggests several lines for epidemiological and laboratory investigation

ACCORDING TO OUR CLOTH

GIVE some men a few packing cases and a packet of screws and they will make a passable dining room suite, others will split the wood for kindling, and some, giving the whole thing up, will leave it to rot in the rain These are the differences between the able, the average, and the problem outlook

That gift for improvising, of which, in war time, we are so rightly proud, has now some special opportunities in the health service The Newcastle Regional Hospital Board,[1] reviewing their charge in 1948, found a shortage of hospital buildings and great inequalities in staffing and equipment Some parts of the region had about enough hospital beds, but few had adequate X ray departments or pathology laboratories, and none had adequate outpatient departments There was nothing like enough accommodation for the tuberculous, *the mentally ill, or the mentally defective* To bring this all up to a uniformly high level, the board saw clearly, would take many years and much rebuilding They would like to be able to build 3 new general hospitals, 3 new sanatoria, and a new mental hospital, and to extend and adapt some 25 existing general and special hospitals, but they realise that for ten years or more they must spend much of their capital allowance on improving what already exists New hospitals, they say, cost £2500 or more per bed, but a bad hospital may be transformed for less than £500 per bed, and greatly improved for an outlay of only £50 per bed They have therefore given to both patients and staff the immediate benefits which come of redecorating, refurnishing, and the removal of extra beds from overcrowded wards Hospital management committees have been given the means to buy good beds and mattresses in place of very poor ones, and each committee has been given £1 2*s* per bed per year to spend on minor capital works of their own choosing The board hope to increase this allocation in the coming years

Staffing, they find, can be improved astonishingly quickly The regional nursing officer has helped management committees to develop comprehensive schemes for training nurses and nursing cadets, and as a result nursing recruitment has improved wonderfully, not only in many general hospitals of the region but in a mental hospital and a mental deficiency hospital as well Working with the dietetic officer of the Ministry of Health, she has also improved the feeding arrangements of patients and staff The main advance in staffing, however, has been in the specialist service The time given by consultants and senior hospital officers has increased by 55%—over half as much again All consultants who came into the service of the board in July, 1948, were allowed to increase their half day sessions to 9 per week, or to become whole time consultants, and additional consultants were appointed either for 9 sessions weekly or full time, at their own choice As a result, consultants are now uniformly distributed through the region—a remarkable achievement in two years—and this has been done by levelling up, not levelling down even such favoured areas as Newcastle, Carlisle, and Sunderland, which had relatively large consultant staffs before the service began, have been able to increase these staffs since 1948 Moreover, the convenience of the consultants themselves has been considered, their sessions being arranged so that they give all, or nearly all, their service in one group of hospitals, and no longer have to go from one end of the region to the other This conservation of their energy costs nothing and is much appreciated

The board have a five year plan for further expansion of the consultant service which financial stringency may prevent them from completing, but they think that, in any new appointments which are made, the tuberculosis service, the mental health service, and the backward parts of the region should have preferential treatment Where consultants are too few, they find, examination, diagnosis, and treatment are sometimes neither efficient or quick, and this leads to extravagance in the use of beds patients are taken in unnecessarily, or stay in too long

> "A hospital spending £1 10*s* weekly on its consultant service and £12 weekly per patient on all services may well be a much more economical as well as a much more efficient hospital than one spending 10*s* weekly per patient on its consultant services and £8 weekly per patient on all services"

They also believe that a regional board which expanded the consultant service to absorb an eighth of the total cost of the service would have found the quickest way to raise the quality of the service to the standard of the best hospitals in the region But they point out that the consultants in such an enlightened service would have to accept the important duty of keeping expenditure down to a minimum consistent with good care of the patients

HIRSCHSPRUNG'S DISEASE

THE American pædiatric surgeons, Swenson and Bill,[1] began to treat Hirschsprung's disease by rectosigmoidectomy at the Boston Children's Hospital over 3 years ago, and soon afterwards Mr F D Stephens, of the Hospital for Sick Children, Great Ormond Street, after visiting Boston, adopted their technique with some modifications in detail In January, 1949, Bodian and his colleagues [2] published encouraging preliminary results in 12 cases, but it was clear that the value of the treatment could not be judged until the patients had been observed for several years The surgeons at Great Ormond Street have now operated on 37 cases and have followed 23 of these patients for a minimum period of a year, and 12 for at least two years The clinical results, reported by Dr Bodian and his colleagues in this issue (p 302) are highly satisfactory There have been 3 deaths, and 2 cases have been followed for less than six months, but the remaining 32 are all in good general condition and 31 of them are having regular and spontaneous bowel actions The Boston results are equally good,[3] and these two groups of workers have undoubtedly established rectosigmoidectomy as a sound and reasonably safe operation capable of producing a lasting cure in most cases

Rectosigmoidectomy is nevertheless a serious operation, and a task for the future, as with many other congenital malformations, is to search for means of prevention This will depend on a better understanding of the interplay of the genetic and environmental factors Now that Hirschsprung's disease has been clearly defined pathologically from other types of megacolon, it has been possible to attempt a genetic analysis of the condition Bodian, Carter and Ward have made a start by investigating the families of their 40 cases and it is to be hoped that other centres will follow suit One valuable fact has already emerged that the chances of brothers of children with Hirschsprung's disease being affected are about 1 in 4 or 5—an appreciable risk—whereas for sisters the chances are much lower

What is the explanation of the remarkable absence of intramural ganglion cells found histologically in a part of the bowel which looks normal to the naked eye? Unfortunately, the early stages of the development of Auerbach's and Meissner's plexuses are not yet fully

understood Some authorities suggest that the intestinal neurones have a vagal and pelvic parasympathetic origin On the other hand, van Campenhout[4] has produced evidence in favour of their development from the thoraco lumbar neural crest Again, Weber[5] suggests a local differentiation of neuroblasts in the mesenchyme of the gut wall Whatever the origin of the intestinal ganglion cells may turn out to be, Bodian and Carter point out that the characteristic distribution and variable length of the lesion in Hirschsprung's disease can be explained in terms of a disturbance affecting at variable stages the differentiation of intestinal neurones in a craniocaudal direction On embryological grounds, the disturbance probably occurs between the 30th and 35th days of fœtal life, and although a definite genetic factor has been established it would be worth while keeping a close eye on the antenatal history of the mothers of these children, especially in the 4th and 5th weeks of pregnancy Some "trauma"—whether infective, nutritional, or otherwise—may play a secondary part in the ætiology

SOME FAMOUS DUBLINERS

Let bygones be bygones," the Englishman is apt to say—or anyhow to think—when confronting an Irish patriot moved by his country's history But what bygones! There was a time, as Mr William Doolin[6] reminds us, when the Irish were specifically excluded from the Dublin Guild of Barber Surgeons, though this piece of oppression, to be sure, was less villainous than it sounds, for the guild was founded in 1446 to tend the injuries sustained by the English soldiers in the defence of Dublin against the Irish The futile device of keeping the Irish out of their own institutions reached a peak at the end of the seventeenth century when the Irish Catholics who had supported the Stuarts were finally defeated, their lands being given to English settlers, and their religion proscribed They were excluded from the franchise, from the Bar and the Bench, from a seat in Parliament, and from any office under the Crown, and they were not even allowed to cut hair The oath of admission to the Guild of Barber Surgeons contained the ordinance "You shall not take any apprentice but of the Protestant religion " The English settlers became the founders of a new class, Protestant and Liberal, the Anglo Irish

The penal code against the Irish was, Mr Doolin says, of unparalleled severity, but he manages to be very good humoured about it, weighing the outcome of those times in a steady balance "To those privileged aristocrats of eighteenth century Dublin, we—Irish as well as English—owe a lasting debt" They gave us Swift, Berkeley, Steele, Goldsmith and Sheridan, Burke and Grattan, Thomas Moore, but no great doctors, for there was no school of medicine in Ireland until 1711, when the anatomy house was built in Trinity College, largely through the energy, foresight, and generosity of an Aberdonian, Sir Patrick Dun Yet even in 1741, when three King's professorships were founded in Trinity, there was the proviso that "all Papists shall be *utterly incompetent of being elected* " An Irish answer came to that in due course Sylvester O'Halloran, of Limerick, came back from Paris to practise medicine, and in 1764 put forward proposals for the advancement of surgery in Ireland a "convenient edifice" should be erected and three professors appointed, a register of practising surgeons should be compiled, candidates should apply for public examination, and the course should be attended with no kind of expense to the candidate, and should be "free to all Irishmen *only* without distinction" In 1780 the Dublin Society of Surgeons was established, and a year or two later the Barber Surgeons Guild was dissolved The surgeons were authorised to found their Royal College (but given no Government funds for the purpose)

In the eighteenth century Dublin contributed to British medicine the idea of the voluntary hospital, and of the special maternity hospital In the nineteenth century it gave the work of two outstanding men, Abraham Colles, an Anglo Irishman, and James Macartney, an Armagh man of Scottish stock, and men of note among the Irish-born trained in the Dublin schools are Alcock Crampton, Houston, Jacob, Porter, Todd, and later Macalister and Wilde

HALF A CENTURY OF ORTHOPÆDICS

The current issue of the British volume of the *Journal of Bone and Joint Surgery* is devoted to a retrospect of progress in orthopædic surgery during the past fifty years Sir Reginald Watson Jones has collected a team of contributors from the world over to trace the developm patterns in America, Great Britain, the Dominions, and continental Europe

Leo Mayer of New York, describes the founding of the American Orthopædic Association and its subsequent growth, gives us vignettes of the grand old men of the period, and reminisces on Anglo American orthopædic comradeship in the field during the first world war under the leadership of Robert Jones and Joel Goldthwait Eminent United States authorities sum up their countrymen's advances in surgical technique, in the orthopædic application of biochemical discoveries, and in orthopædic research and education, and they remind us of the vast responsibilities of public authorities and orthopædists alike to the *crippled in peace and war* Sir Harry Platt tells of the great figures and pioneers in France, Belgium, Holland, Italy, Scandinavia, and Middle Europe, and gives a glimpse, as through a glass darkly of that enigmatic and oddly named man—Henry Turner of Leningrad Canadian orthopædics is the subject of a group of authors which includes R I Harris and W E Gallie, Jackson Burrows gives a sympathetic account of the Australian scene and other reports deal with New Zealand, South Africa, and Southern Rhodesia

But it is Osmond Clarke's survey of the men and events of the half century here in Britain that will stand out for most readers at home Polished, mildly nostalgic, yet alert and forward looking, it brings the mighty names which star his pages to life in vivid word pictures Robert Jones and Agnes Hunt, Muirhead Little and T P McMurray, Tubby, Hey Groves, Arbuthnot Lane, Trethowan, Elmslie, Naughton Dunn, and Lambrinudi, these are some of the giants—joined in the shades as this volume was in the press by that great and kindly man, Gathorne Girdlestone—on whose shoulders we have climbed and whom Osmond Clarke brilliantly portrays They are summed up in two reproductions one the unforgettable painting of Hugh Owen Thomas from the National Portrait Gallery, and the other a photograph of Robert Jones and Agnes Hunt walking together in the grounds of their early cripples' hospital at Oswestry Lloyd Griffiths presents some of the classics of British orthopædic literature, and the volume concludes with a collective review of intramedullary nailing in fractures, and a study of orthopædic endocrinological interrelations by Leonard Simpson

Sir Reginald Watson Jones has re created for us at just the right moment the spirit and atmosphere of an all important period before its memories have entirely faded

The next session of the General Medical Council will open on Tuesday, Feb 27, at 2 P.M, when Prof David Campbell, the president, will take the chair

MUNCHAUSEN'S SYNDROME

RICHARD ASHER
M.D Lond , M.R C.P

HERE is described a common syndrome which most doctors have seen, but about which little has been written Like the famous Baron von Munchausen, the persons affected have always travelled widely , and their stories, like those attributed to him,[1] are both dramatic and untruthful Accordingly the syndrome is respectfully dedicated to the baron, and named after him

The patient showing the syndrome is admitted to hospital with apparent acute illness supported by a plausible and dramatic history Usually his story is largely made up of falsehoods , he is found to have attended, and deceived, an astounding number of other hospitals , and he nearly always discharges himself against advice, after quarrelling violently with both doctors and nurses A large number of abdominal scars is particularly characteristic of this condition

That is a general outline , and few doctors can boast that they have never been hoodwinked by the condition Often the diagnosis is made by a passing doctor or sister, who, recognising the patient and his performance, exclaims "I know that man We had him in St Quinidine's two years ago and thought he had a perforated ulcer He's the man who always collapses on buses and tells a story about being an ex submarine commander who was tortured by the Gestapo " Equally often, the trickster is first revealed in the hospital dining room, when, with a burst of laughter, one of the older residents exclaims "Good heavens, you haven't got Luella Priskins in again, surely ? Why she's been in here three times before and in Barts, Mary's, and Guy's as well. She sometimes comes in with a different name, but always says she's coughed up pints of blood and tells a story about being an ex-opera singer and helping in the French resistance movement "

DIAGNOSIS

It is almost impossible to be certain of the diagnosis at first, and it requires a bold casualty officer to refuse admission Usually the patient seems seriously ill and is admitted unless someone who has seen him before is there to expose his past Experienced front gate porters are often invaluable at doing this

The following are useful pointers

1. (Already mentioned) a multiplicity of scars, often abdominal
2. A mixture of truculence and evasiveness in manner
3. An immediate history which is always acute and harrowing yet not entirely convincing—overwhelmingly severe abdominal pain of uncertain type, cataclysmal blood loss unsupported by corresponding pallor dramatic loss of consciousness, and so forth
4. A wallet or handbag stuffed with hospital attendance cards, insurance claim forms and litigious correspondence

If the patient is not recognised by an old acquaintance, the diagnosis is only gradually revealed by inquiries at other hospitals Some have given so much trouble elsewhere they have been placed on hospital black lists Often the police are found to know the patient and can give many helpful details Gradually the true history is pieced together and the patient's own story is seen to be a matrix of fantasy and falsehood, in which fragments of complete truth are surprisingly imbedded. Just as the patient s story is not wholly false, so neither are all the symptoms , and it must be recognised that these patients are often quite ill, although their illness is shrouded by duplicity and distortion When the whole truth is known, past history sometimes reveals drug-addiction, mental hospital treatment, or prison sentences, but these factors are *not constant*, and the past may consist solely in innumerable admissions to hospitals and evidence of pathological lying Often a real organic lesion from the past has left some genuine physical signs which the patient uses (to quote Pooh Bah) " to give artistic verisimilitude to an otherwise bald and unconvincing narrative "

SOME CHARACTERISTIC FEATURES

Most cases resemble organic emergencies Well-known varieties are

1. The acute abdominal type (laparotomophilia migrans) which is the most common. Some of these patients have been operated on so often that the development of genuine intestinal obstruction from adhesions may confuse the picture
2. The hæmorrhagic type, who specialise in bleeding from lungs or stomach, or other blood loss They are colloquially known as " hæmoptysis merchants " and " hæmatemesis merchants."
3. The neurological type, presenting with paroxysmal headache, loss of consciousness, or peculiar fits

The most remarkable feature of the syndrome is the apparent senselessness of it Unlike the malingerer, who may gain a definite end, these *patients often* seem to gain nothing except the discomfiture of unnecessary investigations or operations Their initial tolerance to the more brutish hospital measures is remarkable, yet they commonly discharge themselves after a few days with operation wounds scarcely healed, or intravenous drips still running

Another feature is their intense desire to deceive everybody as much as possible Many of their falsehoods seem to have little point They lie for the sake of lying They give false addresses, false names, and false occupations merely from a love of falsehood Their effrontery is sometimes formidable, and they may appear many times at the same hospital, hoping to meet a new doctor upon whom to practise their deception.

POSSIBLE MOTIVES

Sometimes the motive is never clearly ascertained, but *there are indications that one of the following* mechanisms may be involved

1. A desire to be the centre of interest and attention They may be suffering in fact from the Walter Mitty syndrome[2] but instead of playing the dramatic part of the surgeon, they submit to the equally dramatic rôle of the patient
2. A grudge against doctors and hospitals, which is satisfied by frustrating or deceiving them
3. A desire for drugs.
4. A desire to escape from the police (These patients often swallow foreign bodies, interfere with their wounds, or manipulate their thermometers)
5. A desire to get free board and lodgings for the night, despite the risk of investigations and treatment

Supplementing these scanty motives, there probably exists some strange twist of personality Perhaps most cases are hysterics, schizophrenics, masochists, or psychopaths of some kind but as a group they show such a constant pattern of behaviour that it is worth considering them together

ILLUSTRATIVE CASE RECORDS

Three cases of the abdominal type of Munchausen's syndrome are described below , for they show clearly the typical features of the advanced form of the disease Many other milder forms have been encountered, but it would be tedious if more were described All the names used in these case histories have been altered, though most of the names were false to start with; but doctors who have met any of the patients may find that the changed name gives a clue to the original one.

[2] Thurber J The Secret Life of Walter Mitty My World and Welcome to It. London 1942

I

A man of 47, giving the name Thomas Beeches, was transferred to the Central Middlesex Mental Observation Ward on May 16 from Harrow Hospital. He had been admitted there on May 13 with suspected intestinal obstruction; laparotomy had shown nothing abnormal. After the operation he had accused the ward sister of tampering with his wallet while he was under the anæsthetic; he had become truculent and demanded his discharge, and because of his violence, and his foolhardiness in wanting to walk out with a day old laparotomy, he was sent for mental observation.

On examination he was rational and convincing. His abdomen was a mass of scars of various vintage. He explained that while in the Merchant Navy in 1942 he had been torpedoed, suffering multiple abdominal injuries. He was then taken prisoner by the Japanese and kept in Singapore till 1945. Throughout this time he had multiple discharging fæcal fistulæ. In 1945, after the liberation of Singapore, he had been taken to Freemantle where he had eleven operations in 7 months (to close the multiple fistulæ), since when he had been continuously at sea till 4 days previously.

The characteristic Munchausen flavour of this history led to further inquiries which revealed that only 8 days previously, while supposed to be at sea, he had been in St. James' Hospital, Balham, complaining of acute abdominal pain; and that a year before that he had been in the same hospital and again behaved in the same way. It was further found that in 1943, when he should have been in Singapore, he had been admitted to the Central Middlesex Hospital complaining of "bursting open of an old torpedo wound" with a discharging sinus in the right iliac fossa. He had then told such a bewildering series of different stories that he had been transferred to Shenley Hospital as a chronic delinquent psychopath, where he was observed for 2 months and then discharged. At Shenley it was discovered that he had a long history of delinquency and had three past convictions for crime, as well as having been twice in West Park Mental Hospital. (He had escaped both times.) On this present occasion no certifiable abnormality could be found and he was discharged on May 19, 3 days after admission. No doubt he is still going from one hospital to another.

A fortnight later, a surgical registrar, knowing my interest in Munchausen's syndrome, produced the notes of a case he had encountered at the Norfolk and Norwich Hospital. It was interesting but not surprising to find that it was the same patient. The notes showed that a Thomas Beeches had been admitted on June 23, 1949, as a case of acute intestinal obstruction. He told a story of having been 33 years in the R.A.F. and of having been shot down over Mannheim in 1942, after which he needed "eight abdominal operations and three short circuits." After treatment with morphine, intravenous drip, and gastric suction, he refused a laparotomy and discharged himself against advice on June 26.

II

A woman of 29, giving the name of Margaret Coke, was admitted on June 13, 1948, complaining of 3 days' severe abdominal pain and vomiting. Her abdomen was a mass of scars. Though admitted from an Edgware address, she gave a home address in Houston, Texas, and said that all her previous operations had been done there, some of them by a "horse doctor." Clinically, she appeared to have subacute intestinal obstruction and was treated with morphine and a Miller Abbot tube; but she discharged herself on June 19 at her own request.

Three weeks later, on July 3, a woman calling herself Elsie Silverborough was admitted to another ward at the Central Middlesex Hospital, having been found collapsed in the street by the police. She gave a home address in Lancashire. It was found she had discharged herself that day from Wembley Hospital, where she had been admitted on the previous day for suspected acute intestinal obstruction. As before, she had been found by the police collapsed in the street. Elsie Silverborough told a story of having had all her previous operations at the Manchester Royal Infirmary, but a surgical registrar recognised her as the Margaret Coke who had been operated on by the Texas horse doctor, and they were proved to be one and the same person.

Inquiries at Manchester Royal Infirmary revealed no trace of either Margaret Coke or Elsie Silverborough having been there; but the day after the identities of these two persons had been merged, a surgical houseman recognised the patient as a certain Elsie Packoma whom he had encountered twice at the Royal Northern Hospital on Oct. 27, 1947, and Nov. 13, 1947. On both occasions she had arrived in casualty smelling of drink and complaining of retention of urine. On the first occasion she was catheterised and then refused all treatment, refused to sign the book or to be admitted, and said she was going to a hotel to call in her private doctor. On the second occasion, she was recognised by the casualty officer and made off before a doctor had seen her. Further inquiries at the Manchester Royal Infirmary revealed that an Elsie Packoma, with a scarred abdomen and a Manchester address, had been admitted as a case of intestinal obstruction on Nov. 15, 1947—two days after discharging herself from the Royal Northern Hospital. No operation had been performed. She had been treated with morphine, Ryle's tube, and enemata, and discharged herself against advice 2 days after admission.

The triad of Margaret Coke, Elsie Silverborough, and Elsie Packoma was discharged from the Central Middlesex Hospital on July 6, 1948, and nothing further has been heard of it. She told us before she went that she had lived in Piccadilly nearly all her life, working as a prostitute.

III

A woman of 41, giving the name Elsie De Coverley, was admitted to the Central Middlesex Hospital on Feb. 7, 1950, having collapsed on a bus. She gave a history of 2 days' melæna and 1 day's severe abdominal pain with vomiting of dark blood. On examination she was apparently in severe pain. Her abdomen was a mass of scars and her veins showed marks of many "cutting down" operations. Her heart showed a mitral presystolic murmur. She told us that in the last 5 years she had had two operations for perforation, one for gastro-enterostomy and one for intestinal obstruction, all done at the Royal Devon and Exeter Hospital, where she said she was due to return for a partial gastrectomy.

At first she was diagnosed as a case of a bleeding ulcer with probably a small perforation, but despite her severe pain there was no abdominal rigidity and radiography showed no gas under the diaphragm. Her hæmoglobin was 90% and her stools gave only a weakly positive benzidine test. A telephone message to the Royal Devon and Exeter Hospital revealed that she had only once been there in 1944 and had never had an abdominal operation there, but that many other hospitals had made inquiries about her. The patient continued to complain of severe abdominal pain, and a barium meal and gastroscopy had been arranged when she discharged herself against advice on Feb. 15, saying that nobody really thought she had pain.

Since that time an attempt has been made to find out about her past, and here the Royal Devon and Exeter Hospital have been most helpful, because they have been able to trace much of her progress round the country by noting the hospitals that asked after her. More inquiries at these hospitals have each disclosed more admissions at other hospitals, and the complexity of the patient's wanderings grew in the manner of a snowball. I had not the time or the patience to pursue the meanderings completely and the fact that she was found to use nine different names made the project more formidable. The following list of some of her activities is probably incomplete.

In February, 1944, she was admitted to the Royal Devon and Exeter Hospital as Elsie De Coverley from Exeter Prison, with epistaxis.

On April 9, 1947, she was admitted to the Croydon General Hospital as Miss Joan Morris, a shorthand typist, giving long history of dyspepsia and hæmatemesis While being reated with rest and diet she discharged herself 2 days later

From Oct 31 till Nov 16, 1947, she was in the Royal Sussex Hospital, giving the name Joan Summer, and suspected of having a bleeding leaking ulcer, but at operation the findings were subacute obstruction from adhesions and scarred duodenal ulcer Gastrojejunostomy was performed She discharged herself on Nov 16 against advice, still complaining of severe abdominal pain

On Dec 10, 1947, she was admitted to the Croydon General Hospital with acute abdominal pain, ' doubled up in agony," as Mrs Elsie Layton, a district nurse She said she was awaiting a partial gastrectomy in Birmingham Hospital Efforts made to contact her relatives showed that the names and addresses were all false and the patient discharged herself on Dec 12 She was admitted to Redhill County Hospital a few days after leaving Croydon She again gave a similar story and discharged herself within a few days

From Jan 29 to March 29, 1948, she was in Paddington Hospital, again as Joan Summer, and a laparotomy for bleeding duodenal ulcer was performed, later she complained of severe anginal pain and discharged herself after giving much trouble in the ward

In March, 1948, she was in the West London Hospital as Joan Lark with alleged pain and bleeding, and discharged herself

From April 6 to 9, 1948, she was in Fulham Hospital as Joan Summer giving a history of having all her previous operations in York (inquiries at York failed to trace her), and again presenting with alleged abdominal pain and hæmatemesis On April 9 she was recognised by a surgeon as Joan Lark of the West London and discharged herself that day

On July 10, 1948 she was admitted to Guy's Hospital as Joan Malkin, but later said this was an assumed name and gave the name Joan De Coverley, and said all her previous operations had been done at Edinburgh (Edinburgh denied knowing her) At Guy's she was suspected of having a perforated ulcer, but a laparotomy on July 10 showed nothing abnormal except a mass of adhesions, and she discharged herself on July 13, only 3 days after the operation, and never returned to have her stitches out

On Jan 6, 1950, she was admitted to the Royal Free Hospital as Elsie De Coverley, with the usual story She complained of continuous pain and discharged herself on Jan 11, saying her sister had just died (At many hospitals she has given a story of a dying sister)

On Jan 18 she was admitted to St Mary Abbots Hospital still as Elsie De Coverley, having collapsed in Kensington High Street with alleged pain and vomiting of blood On Jan 20, when told she was not going to have an operation, she pulled out her stomach tube and demanded her immediate discharge

Later the same day, she was admitted to University College Hospital, and she had a laparotomy on Jan 25 for suspected perforation Nothing was found except adhesions The usual self discharge followed on Jan 30

The same day she was admitted to St Bartholomew's Hospital and discharged herself on Feb 2

From Feb 7 till 15 she was in the Central Middlesex Hospital—see the description at the beginning of this story

Since leaving us she has remained active, because on March 7 she arrived at the Elizabeth Garrett Anderson Hospital as Jean Hops and was transferred via the Emergency Bed Service to the Royal Free Hospital The transfer was unfortunate for her because she was recognised by the ward sister and registrar at the Royal Free, where she had been under another name in January this year, and she discharged herself immediately

On March 27 she was admitted to Middlesex Hospital as Elsie De Coverley, with the usual story of pain and hæmatemesis, where she remained for three days She discharged herself when she learnt that inquiries were being made about her at the Royal Devon and Exeter Hospital

On April 12 she was admitted to the Croydon General saying she was awaiting a partial gastrectomy at the Royal Devon and Exeter Hospital, and giving a history of severe abdominal pain and bleeding The Croydon General rang the Royal Devon and Exeter Hospital and while the telephone conversation was being conducted she got out of bed, dressed, and made off

On April 17 she turned up in Hackney Hospital as Elsie Shackleton, and that is the last that has been heard of her Probably she is now careful to avoid mentioning the Royal Devon and Exeter Hospital, who have repeatedly exposed her in the past, and, with new names and a slightly different story, is continuing to deceive the few remaining hospitals which she has not yet visited

It seemed worth publishing this rather tedious itinerary in full to show the lengths to which a case of Munchausen's syndrome can develop, and also because it may be a help to surgeons and physicians who are confronted by her case in the future

CONCLUSION

The syndrome of Baron von Munchausen has been described and three typical cases reported

These patients waste an enormous amount of time and trouble in hospitals If any correspondence follows this account, exposing other cases, perhaps some good will have been done It would be even better if an explanation for the condition could be found, which might lead to a cure of the psychological kink which produces the disease

I wish to thank the many doctors and records officers who supplied information about these cases, particularly Mr K P S Caldwell who traced most of the migrations of case 3

COST OF HOSPITALS

Some Facts from Scotland

THE Department of Health in Edinburgh has been working away industriously at hospital " cost " statistics The obligation to make good use of the material now coming to hand in respect of the six Scottish regions for 1949–50 is clearly felt strongly The department deserves a good mark—not yet earned by the Ministry of Health in London, or by any of the regions in England and Wales—for coming forward and offering its efforts for publication and criticism

Much of this material is of considerable interest It is based on the first full year's figures available—i e, 1949–50, when the total bill for Scotland, including specialist services, was £21,933,000 A total showing the relative importance of the several elements in the hospital cost proper, which amounted to £17,691,000, shows the following picture

	% of total	
Patients food	9 8	
Patients clothing and laundry	3 1	
Drugs dressings surgical appliances &c	6 1	
1 COSTS ATTRIBUTABLE TO PATIENTS		19 0
Maintenance of buildings and grounds	2 7	
Domestic repairs and replacements	6 0	
Fuel light and power	8 2	
2 COSTS ATTRIBUTABLE TO BUILDINGS		16 9
3 MISCELLANEOUS—administration transport travelling amenities trading services rent and rates &c		4 9
Staff food laundry and uniforms	4 5	
Salaries and wages—junior medical staff	2 3	
—nursing staff	28 8	
—administrative staff	4 3	
—other staff	19 3	
4 COSTS ATTRIBUTABLE TO STAFF		59 2
Total		100 0

Commenting on these figures the Secretary of State has pointed out that it is thus clear that most of the money is going on staff salaries and upkeep and that control over staff establishment is therefore of decisive importance as a means of ensuring economy Expenditure, however, on the salaries of those who are solely concerned with administrative and clerical work of the hospitals represents only some 2½% " In the light of these figures," he said, " it does seem to me to be sheer nonsense to talk wildly of saving millions on the Health Services by slashing administrative waste in the hospitals "

Another total shows the costs of hospital beds per day category by category The department uses for this purpose a "composite" cost of its own devising, built up in an effort to strike a useful compromise between the cost per occupied bed and cost per bed calculated on the complement irrespective of occupancy This method no doubt has merit, but it is perhaps a pity to use it without showing also a straight cost per occupied bed, which, despite its well known defects, has been widely adopted in hospitals in Great Britain

	Composite rate s	d
General hospitals—		
1—50 beds	21	11*
51—300 beds	2[illegible]	[illegible]
301—900 beds	26	8
All general hospitals	2[illegible]	7
Infectious diseases hospitals	22	9
Maternity hospitals	37	8
Tuberculosis sanatoria	20	0
Convalescent hospitals and homes	15	4
Mental hospitals	11	6
Mental deficiency institutions	10	4
All hospitals	18	4

* To the nearest 1d

The department offers this table as a yardstick against which the regional boards would be wise to check the costs of individual hospitals, and by way of emphasising this examples are given of groups of presumably comparable hospitals showing wide variations from the average cost, for example, mental hospitals are compared

> "Most of them are fairly large, their functions are similar and their rates of occupancy are uniformly high There are a few wholly exceptional ones but these are all omitted from the comparisons below The composite occupied bed day rate for all mental hospitals in Scotland is 11s 6d The highest figure for any single hospital is 16s 9½d, the lowest is 7s 5½d If the national mean is taken as 100, there are two hospitals under 70 and five more under 80, there are, also, three over 130 These variations make a big difference in the annual expenditure The rate of 16s 9½d for the hospital in question represents an annual expenditure of £31,140 more than the average rate of 11s 6d would produce, the rate of 7s 5½d represents an annual expenditure of £32,374 less It is hard to believe that these wide variations can be accounted for except by substantial differences in standards of accommodation and of care and treatment and the abnormally low costs must be a matter for serious concern as well as the abnormally high"

The regions are urged to look into these matters, but here the department has to confess its bankruptcy In the absence of a system of departmental analysis it cannot offer any further help at the point at which it is really needed The Secretary of State did say that it is proposed "to tackle also the comparative analysis of expenditure in various fields" and to look first at things like food costs, fuel, light and power, and that another possibility would be to compare two X ray departments one with another But is this going far enough? The urgency and the fundamental importance of a proper system of departmental analysis of expenditure does not seem to have been grasped Tables similar in principle to those now offered by the department were available for the former voluntary hospitals in London through the King's Fund's statistical summary for the last fifty years, it is primarily the fact that such tables, though most useful, are no more than an unsatisfactory half way house that has led the Minister of Health to set on foot the important investigation into hospital costing now being undertaken by King Edward's Hospital Fund for London and the Nuffield Provincial Hospitals Trust

But the Department of Health has also branched out in another direction It has prepared data comparing one region with another under a variety of headings, and has ventured to set down data comparing beds to populations Ever since serious quantitative discussion of hospital affairs began in the '30s, assuming the possibility of a comprehensive service, it has been evident that what is really a new science of hospital provision was about to dawn upon us Here now at last is the first serious set of figures based on a whole year and comparing sizable areas one with another It has always been suspected that the figures when produced would show substantial variations from the norm, and so they do

—	Northern	North eastern	Eastern	South eastern	Western	Scotland
Beds per 100 000 of population	99	85	128	89	103	100 = 1[illegible]
Ratio of nurses to staffed beds	84	112	95	106	98	100 = 0[illegible]
Ratio of nurses to staffed beds excluding mental hospitals and institutions	83	114	98	107	95	100 = 0[illegible]
Ratio of other staff to staffed beds (excluding doctors and nurses)	81	83	112	105	100	100 = 0·43
Ratio of specialists to staffed beds	100	100	84	113	98	100 = 16[illegible] per 1000
Ratio of specialists to population	107	97	114	99	99	100 = 1 3 per 10 000
Annual specialist costs per staffed bed	92 3	99 7	72 9	122 9	97 7	100 = £17 1[illegible]
Annual specialist costs per head of population	93 8	89 5	100 8	106 3	98 4	100 = 10s [illegible]
Composite in patient day rate	99 5	95 9	97 3	99 6	101 4	100 = 18s [illegible]

On this head the department is certainly to be congratulated, not so much for its achievement as for setting sail on an uncharted sea Who is going to be the first to devise the really instructive way of handling data such as these? Who is going to be able to say that there, and there, and there, are hospitals that work twice as effectively or twice as cheaply as the others? The Department of Health think that "unless there are special circumstances to the contrary in any particular Region it should be the first object of policy to encourage developments in those particular fields in which the Region is least favourably placed" But is this the right way to look at it? May the signs not be read to mean that these are precisely the fields in which success has been achieved or where perhaps preventive factors in their widest sense are most effectively deployed? It would be a pity if such useful tables were to be read in the light of the assumption that progress is synonymous with increasing hospital services May we hope that in each Scottish region at least one medical officer of health will fasten upon the data and try to see that they are read the right way up and not the wrong way down

---

"The influence of mind on body was recognised long before anyone began to talk of psychosomatic medicine and no doubt there were many family doctors in the nineteenth century who were just as good at treating nervous dyspepsia as anyone is nowadays with Freud or Jung behind them You may remember the heroine of Jane Austen's youthful burlesque who said 'Beware of swoons, dear Laura A frenzy fit is not one quarter so pernicious It is an exercise to the body and if not too violent is I dare say conducive to health and its consequences"—Prof E D ADRIAN, O.M. F R S, *Conquest*, 1951, 38, 2

Medicine and the Law

Secrecy of Service Medical Reports

EXECUTIVE councils have lately been assured that the Admiralty, War Office, and Air Ministry will continue to make available the medical reports of persons discharged on medical grounds from the Forces But, it is stated in E C N 68, the reports are supplied to practitioners in confidence for the sole purpose of helping them in their treatment of the patient, and must therefore not be disclosed either to the patient or to any other party If, continues E C N 68, a subpœna is served on the practitioner to produce a Service medical record in court, the practitioner should not return the report to the Service department, but should at once tell the department so that the responsible Minister can have an opportunity of giving him a certificate claiming "Crown privilege" for it and directing him not to produce it

A year ago we recorded[1] a refusal by the War Office to allow a coroner's court to have evidence of an Army doctor's previous medical examination of a soldier who dropped dead during a course at the Guards' depot at Caterham The coroner adjourned the inquest in the hope that the Army doctor would attend to give the evidence, but the War Office claimed privilege on the grounds of public interest

"Crown privilege," said Lord Simon in Duncan *v* Cammell Laird and Co (1942), the leading case on the subject, "is an unhappy expression" Privilege, in relation to "discovery" (i e, the litigant's obligation to disclose facts and documents which might tend to establish his opponent's case) is for the protection of the litigant and may be waived by him, but the rule that the national interest must not be jeopardised by producing documents which would injure the State is a principle quite unconnected with the interests or claims of the particular litigant Where the document contains information about a patient, there is clearly a sharp distinction between the Crown's "privilege" and the patient's

The Cammell Laird litigation arose out of the sinking of the submarine *Thetis* during her submergence trials in June, 1939 when 99 men lost their lives In a test case against the company the Crown claimed privilege in respect of several documents, including the contract for the hull and machinery, the plans and specifications, the report of the submarine s condition when raised and a foreman painter s note book The First Lord of the Admiralty testified in an affidavit that production of these documents would be injurious to the public interest In effect the House of Lords refused to interfere and the significance of Lord Simon s opinion is that he prescribes the considerations which a responsible Minister must have in mind when making such objections to disclosure It would not be a good ground he said, to contend that, if the documents were produced, the consequences might involve the department or the Government in parliamentary discussion or public criticism or might necessitate the attendance as witnesses or otherwise of officials who have pressing duties elsewhere The Minister must not refuse disclosure on the ground that it might tend to expose a want of efficiency in the department or to lay the department open to claims for compensation It was not enough that the department should want non disclosure There must be some such ground as that disclosure would be injurious to national defence or to good diplomatic relations, or that the practice of keeping a class of documents secret was necessary for the proper functioning of the public service

If a discharged soldier's medical history sheets are kept secret even from himself, the War Office presumably justifies the secrecy as "necessary" in that sense

Before the Crown Proceedings Act of 1947 came into operation, the Crown, when a party to a suit, could never be ordered by a court to make discovery of documents the Act now allows such orders to be made In confirmation, however, of the decision in the Cammell Laird case the Act allows the responsible Minister still to withhold a document on the ground that disclosure would be injurious to the public interest The Act contemplates (and the rules of court made thereunder allow) that the Minister may even conceal the existence of a document if disclosure would be thus injurious

There seems a wide difference of degree between non disclosure of a new submarine's secret plans and that of a soldier's medical record where his own interest may be at stake The Ministry of Health seems to expect that some discharged men will not consent that their Service medical history be disclosed to their doctor in civil life The doctor will have to apply to the executive council on form E C 53, which provides for the patient's consent to disclosure It is a complicated procedure, and the councils may have plenty of documents to file If the only privilege in the case were the professional privilege between doctor and patient, the profession would know how to deal with it

Parliament

Kingston Victoria Hospital

IN the House of Commons on Jan 30 Mr C W BLACK raised once more the position of the Kingston and Malden Victoria Hospital[1] A new situation had arisen, he said, since the beginning of November, when notice had been given to the hospital authorities that no more patients were to be received That order was not complied with by the doctors or the hospital authorities Whatever the legal niceties of the position might be, the action of the doctors and the hospital staffs had been condoned by the regional hospital board, which had continued to pay the salaries and the running expenses connected with the hospital The proposal that this much-esteemed local hospital should lose its independence had been strongly criticised by local and medical opinion After outlining the course of the dispute, Mr Black said he did not ask the Minister at this juncture to override the decision of the regional hospital board, but to set up an independent and impartial inquiry

Sir IAN FRASER said this situation was parallel to that of the Victoria Hospital, Morecambe, and there were about 20 or 30 other towns in the same position He asked the Minister not to confine his answer to the local issue but to deal with the wider issues involved Mr FRED MESSER declared that if the Minister conceded what had been asked he would have trouble from one end of the country to the other The regional hospital boards had been set up to plan the health service. What did not strike Mr Black and those local people who opposed these proposals was that planning would result in an addition to the available beds Mr Messer asked the Minister to let the regional boards get on with their job

Mr H A MARQUAND the new Minister of Health, said that he assumed that they were all in favour of a health service and of a regional organisation for that purpose Reorganisation was bound to affect some of the smaller hospitals which covered the wider range of specialties and yet had few beds and perhaps lacked other facilities. In every one of these schemes such hospitals had to give up some of these specialties and become a unit for one specialty only in order that one adequate unit might be available in every committee group That was the essence of the planning of the regional hospital boards, and consequently the functions of this particular hospital had to be changed for the better service of the public There was no question of animus on the part of the regional board or the Ministry of Health against a general-practitioner hospital as such

It had been found, he continued, that in the Kingston area there was an outstanding need for a first-class gynæcological unit. He was told that there were nearly 300 women on the waiting-list which could not be cut down until the scattered gynæcological facilities were centralised and improved He was sure that the regional board had considered this matter carefully and he did not see why he should reject their opinion that the scheme could not be worked without using the exceptional facilities of the Kingston Victoria Hospital to create there this gynæcological unit That was the place chosen because it was close to the specialised skill and equipment possessed by the Kingston Hospital

---

[1] See *Lancet* 1950 ii 527 832

It was unfortunate that the plan meant that some patients would no longer be able to use this hospital, but there was no doubt that its facilities and 11 beds would be better used for the proposed purpose than in an attempt to deal in such a small compass with all aspects of medical and research work Proper safeguards for the general practitioners using the hospital at present were preserved under this scheme, they were not to be cut off from hospital work altogether and the Surbiton Annexe could, he believed, be made a satisfactory building, and he asked the general practitioners of Kingston for their cooperation The gains, Mr Marquand pointed out, would be substantial Among the six or seven hospitals in the Kingston area there would be 226 beds under the new scheme, as against 203 at present, 102 maternity beds as against 81, and 11 gynæcological beds as against 37 Apart from these increases in beds there would be an increase in facilities There had already been ample inquiry into this matter All the facts were known, and action had to be taken on the basis of those facts If, however, members would like to bring a deputation to him and allow him to explain the scheme in greater fullness he would gladly do that But he was not prepared to hold up the work on the annexe

Cleanliness in Handling Food

In the House of Commons on Feb 2, Dr A D D **Broughton** moved that action should be taken by the Government to encourage cleanliness in the preparation and serving of food in retail shops and catering establishments One of the first essentials, he believed, was clean hands when dealing with food, but there were still food shops with no adequate washing facilities Food-poisoning was increasing, before the war there were 50 outbreaks a year, now there were nearly 1000 most of which had been traced to food eaten or prepared outside the home Communal feeding was increasing and the population were eating more and more made up foods He urged the Government to introduce a Bill requiring catering establishments to register with their local authority, to encourage local authorities to adopt a standard code of practice for catering establishments, and to encourage education in hygiene

Dr **Barnett Stross** held the figure of 1100 persons stated in the report of the Medical Research Council to have been affected by food-poisoning in 1949 to be an underestimate At a guess he thought the number of cases in an average year might be as high as 50,000 with a consequent loss of 100,000–500,000 working days Among the 1100 cases in 1949, there were 58 deaths The Medical Research Council had analysed 339 outbreaks or instances of food-poisoning in 1949, and of these, 222 attacks, or 65%, were traced to meat dishes, and 195 of these were due to made up meat dishes Fish caused 46 outbreaks, or 14%, 30 outbreaks were due to duck eggs, and 5 outbreaks were traced to milk In school canteens there were 68 outbreaks, in works canteens 32, in restaurants and hotels 35, in hospitals and institutions 44 Workers with discharging wounds or diarrhœa must not be allowed to handle food and must be compensated for loss of earnings He believed the fullest medical supervision of workers to be impossible, and anything less was useless But premises could and should be inspected

Mr **Somerville Hastings** was sure that some of the epidemics of food-poisoning associated with minced meat and sausages occurred not because anything was wrong with the food but because the mincing machines had been imperfectly washed Washing up in public restaurants and bars was often imperfect and was a real danger Diarrhœa, ulcerated gums, and influenza, had been traced to that source Recent work suggested that if utensils were put into water at nearly boiling-point for about 30 to 60 seconds, there was little additional danger from cracked crockery Mr Hastings held that authorities should have power to inspect dish-washing as well as the preparation of food There should be two washing-up bowls, and dishes should be dried by air, as towels used for wiping were a great source of danger

Dr **Charles Hill** pointed out that it was food that had been left about, usually milk products and made-up dishes, which was most dangerous The value of refrigeration should not be exaggerated the refrigerator suspended the activities of the germs, but when the food was withdrawn into a warmer temperature the energy of the germs returned unabated For the most part the agency of contamination was flies or fingers The public had to realise that disease carried in the bowel, in the nose or throat, and on the infected skin could be imparted to foodstuffs and lead to disease in hundreds of people. The problem was a restricted one There was no need to put people off their victuals by generalised scare talk The problem arose for the most part from careless or ignorant conduct on the part of food handlers. Prevention could only take place by convincing people of the dangers and that personal conduct would solve the problem. Today, Dr Hill said, it was much easier to engage in such propaganda with candour and frankness than it was some years ago

Mr F T **Willey**, parliamentary secretary to the Ministry of Food agreed that the annual report of the Ministry of Health showed that the number of food poisoning outbreaks had increased from 422 in 1945 to 961 in 1948, and the number of individual cases of food poisoning from 6063 in 1949 to a provisional figure of 7180 in 1950 The increase might be partly due to improved diagnosis but that did not relieve us of responsibility, for if we are more aware of the dangers of food-poisoning, so much greater is the burden upon us to prevent it On the other hand, there were over a quarter million catering establishments serving a large number of meals every day Against this background the risk of food poisoning is infinitesimal Model by-laws had been adopted by 1100 local authorities, and there were many powers for local authorities to use On the question of registration of catering establishments, Mr Willey said there was a difference of opinion among the catering trade working party in the light of their recent report, and it was also too early to give an undertaking to enforce a code of practice on the catering industry It was essential that they should carry the industry with them Health departments were giving all the help they could and the Ministry of Food was doing everything possible to encourage educational activity in food hygiene Until practices which spread food infection were widely known, he thought it would be difficult to make further regulations or legislative changes effective

The motion was agreed to

Penicillin (Merchant Ships) Bill

In the House of Commons on Jan 29 this Bill which has already passed through the House of Lords was reported without amendment and read the third time and passed

QUESTION TIME

Treatment of Tuberculosis

Mr **John Rodgers** asked the Minister of Health if he would inform all local authorities of the facilities available in the country for the rehabilitation of men and women suffering from tuberculosis and the desirability of using these facilities to their full capacity —Mr **Marquand** replied The attention of local health authorities has been drawn, most recently in July last, to the means available for this purpose, and I am sure they will share my view that they should assist in using these means to the full Mr **Rodgers** Is the Minister aware that the British Legion village of Preston Hall in Kent today has 50 vacancies for ambulant ex Servicemen, and will he again impress upon the local authorities their moral obligations in this matter ?—Mr **Marquand** I am sure that this exchange of question and answer will draw attention to the existence of these facilities

Tuberculosis Beds

In answer to a question Mr **Marquand** stated comparable figures are not available for these, but that at Dec 31, 1949, 28,430 beds for tuberculous patients were in commission (including about 1250 beds used in hospitals outside the health service) In England and Wales at present the waiting list as provisionally ascertained was approximately 10,400, about 600 fewer than a year ago This was the first decrease recorded since the war

In answer to further questions Mr Marquand said that the possibility of using the available beds in Switzerland was being considered. He had had two officials in Switzerland looking into the matter, and for technical reasons it had been decided to send at once a senior medical officer to amplify the report already rendered. Discussions were going on with the Chancellor of the Exchequer. Mr Marquand added that he had no power to make grants to tuberculous patients who tried to find accommodation for treatment in Switzerland at their own expense.

Certified Lunatics and the Franchise

Colonel LEONARD ROPNER asked the Minister on what grounds he had decided to extend the franchise to certified lunatics.—Mr MARQUAND replied: The franchise has not been extended. The law is and has been for many years, that apart from idiots, a person suffering from any form of mental disability, if on the electoral register, is entitled to vote if he presents himself at the appropriate polling station and satisfies the presiding officer as to his capacity to do so.

Benefactors of Voluntary Hospitals

Sir JOHN MELLOR asked the Minister if he would identify the powers by which he had instructed benefactors under covenant of voluntary hospitals to pay instalments to him, and if he would refrain from enforcing such claims in the courts.—Mr MARQUAND replied: The powers are contained in section 7 of the National Health Service Act 1946. I am advised that a person who executed a deed of covenant has himself no power to cancel it, and I hope therefore that action in the courts to enforce compliance will not become necessary.

Hospital Consultants

In answer to a question, Mr MARQUAND, the Minister of Health, stated that at Dec. 31, 1949 1309 full-time consultants were in contract with the regional hospital boards. The numbers were highest in the four Metropolitan boards (161–185) and lowest in Oxford (21), Liverpool (39) and Leeds (40).

Number of General Practitioners

In reply to a question Mr MARQUAND stated that the number of general practitioners on the medical list in the National Health Service in England and Wales on July 1, 1950, was 18,710.

Immunisation and Limb Paralysis

Mr S P VIANT asked the Minister whether any record existed of the number of cases of paralysis developing in the inoculated limb, one, two, or three months after immunisation.—Mr MARQUAND replied: Details are available for 1950. In that year 46 cases of paralysis developing in the inoculated limb after immunisation were reported. Of these 35 occurred within one month, 10 in the second month, and 1 in the third month after immunisation.

School Dental Service

Mr GEORGE TOMLINSON, Minister of Education, informed Mr JOHN BAIRD that the number of dental officers in the school dental service at the end of 1950 was equivalent to 717 full-time officers.

Cancer Research

Mr GEORGE THOMAS asked the Lord President of the Council whether he was now able to arrange for an increased grant for research into the causes and cure of cancer.—Mr HERBERT MORRISON replied: Substantial sums are already allocated by the Medical Research Council to research on this important subject and further provision is made by bodies such as the British Empire Cancer Campaign and the Imperial Cancer Research Fund. I am unable to recommend any further grant at this time but a constant watch will be maintained for any new and promising lines of inquiry for which present resources may be inadequate.

Replying to further questions Mr Morrison said the expenditure of the Medical Research Council for the current financial year on the cause and cure of cancer is estimated at £157,400. Further expenditure was expected to be incurred during the coming financial year. In so far as promising lines of research opened themselves the Government would be ready to spend money, but the spending of money in advance of research would be silly.

Mr SOMERVILLE HASTINGS: Has there been any demand from responsible members of the Medical Research Council for more money to be spent on cancer research?—Mr MORRISON: I think not, Sir.

In England Now

A Running Commentary by Peripatetic Correspondents

THESE economist chaps seem agreed that, if we are to maintain our present fancy standard of living, we must increase productivity. Unless my educativity has been sadly neglected, productivity doesn't mean much more than production or output, and I suppose the only way you can increase your output is by putting more time to it. None of us, of course, works as hard as he thinks he does, but I have been musing on the case of my friend, patient, and fellow-worker, Fred, who drives the lorry for the Council. Fred works a 44-hour week and has a fortnight's annual holiday with pay. His health is generally good but he's apt to get flu in the winter and a go of lumbago in the summer. That means another 4 weeks off sick, and he rightly gets public holidays, Christmas Day, *and so forth—call it another week.* Now, if my arithmetic is right, Fred works 44 hours a week for 45 weeks in the year. In other words, out of every 365 days of his life he works rather less than 87. My deductivity is that he is not achieving maximum productivity.

* * *

"Mad Lou," as she was called locally, was brought to our Observation Unit by the Police and the Duly Authorised Officer, together with Exhibit A—the coal-hammer with which she had threatened her neighbours, whom she imagined to be making abusive remarks about her. Since she weighed twenty stone and was muscular in proportion it was easy to understand the consternation she had created. She seemed fairly happy with us, apart from periodic outbursts due to similar hallucinations, but Sister, finding her in tears some days later, discovered that she was grieving for Peter, who turned out to be not a long-lost son but a large ginger-and-white cat, abandoned in Lou's unceremonious departure from home. We made inquiries and found that Peter had been handed over by the Police to the R.S.P.C.A., but Lou had neither family nor friends, and none of the neighbours would adopt her cat, so it seemed that he would have to be destroyed when his mistress, in a few days' time, was removed to a mental hospital under certificate.

The D.A.O., Sister, and I asked all the hospitals in our catchment area, and finally I struck a particularly humane medical superintendent and secured a double vacancy. Lou's delight on hearing that she was to have Peter with her was touching to behold, but when the day came for her transfer to hospital, the ambulance was getting ready outside, and there was still no sign of Peter, she reverted to tearful suspicion, evidently believing she was being lured to her doom by false promises. Fortunately, the R.S.P.C.A. man arrived at the gallop, in the nick of time, with the bewildered Peter in a basket. He had gone by mistake to another hospital nearby, where his breathless inquiries for an ambulance waiting for a cat had led to his being hastily re-directed to us—we felt he was lucky not to have been sent under escort.

Lou, with Peter in his basket, and one of our sisters, were bundled into the ambulance, the Cockney driver remarking drily that he *hoped* his insurance covered cat-bites, and off they went. On the journey, Peter miaowed so piteously that Sister let him spring out of his basket into Lou's arms, where he settled down peacefully. When they reached the hospital Lou still thought the whole thing was a trap, and my friend the superintendent had to come to the ambulance and reassure her personally that Peter would not be taken away from her. The last thing Sister saw of them was Lou lying on a bed in the admission ward clasping the purring Peter to her ample bosom.

Tail-piece.—On phoning a few days later I was told that Lou is settling in happily and that Peter has become the pet of the ward. Lou much prefers her new quarters —"It's not like that Other Place," she remarks with a sniff, "they wouldn't let me 'ave Peter with me *there*." Just as I am digesting this news, Sister enters the clinical room and tells me that Mrs X, an extremely paranoid patient, is now asking why she can't take her three dogs when she goes to hospital tomorrow.

* * *

An interesting panorama of the contemporary French school of art has been assembled at the Royal Academy (L'École de Paris, 1900–50) and will be on exhibition until March 7. There are 162 pictures on view, about a third of them abstract. The five by Matisse illustrate clearly his characteristic drawing, with its intentional distortion, and his love of clear sweeps of bright colour. Kandinsky, the originator of the Abstractionists, is represented by four pictures. His "Violet Dominant" will either make you feel very humble or irritate you extremely. But as he paints to produce an emotion, perhaps this is a measure of his success. Apparently Picasso will not allow his pictures to be shown officially in England, owing to his political convictions. However, the Cubists are well represented, and from these pictures, with their striving for strength through insistence on the straight line and distortion, one can understand their affinity with Communism: they certainly cannot be accused of bourgeois sentimentality. Among these more extreme schools there are some excellent examples of such French Realists as Utrillo, Vuillard, and Bonnard. I found Utrillo's suburban scenes particularly effective, but Marquet's "Docks at Le Havre," Soutine's "After the Storm," Bauchant's "Asters," and Marchand's "Snow Landscape" are all delightful and show that the Paris School is not entirely concerned with Abstract. Those who like searching out psychological motifs will no doubt point to Coutaud's "L'Armoire Chair de la Porteuse de Pain" as a demonstration of coprophilia and to Miro's "Bull Fight" as one of infantilism.

The Academy's exhibition of "Holbein and other Masters of the 16th and 17th Centuries" is still open and will be until March 7—a magnificent collection of early English portraits. Medical visitors should note the large picture of Henry VIII presenting a charter to the Guild of Barber Surgeons and Carlo Dolci's portrait of Sir Thomas Baines (1622–81). The collection includes works by Eworth, Titian, Tintoretto, Van Dyck, Rubens, Raphael, Michelangelo, and Leonardo da Vinci (one), so I need say no more. I found it a welcome relaxation after the École de Paris.

* * *

The series of articles appearing in *The Lancet* on the techniques in Medical Lifemanship are filling a long felt want. A search through the shelves of a well-known medical bookseller has failed to reveal a single textbook on this subject, and it is indeed fortunate that my own two works—*Recent Advances* and *Students' Aids* are nearing completion. Meanwhile the primary purpose of this note is to draw attention to a little known branch of which I, as a pathologist, have made a special study—namely, Labmanship. Labmanship in a laboratory technician may be defined as getting one up on the pathologist, and vice versa. A pretty example came my way the other day. As I was examining the vibrio isolated from a patient's stools I remarked to our Senior Technician: "I don't think it's a *choleræ*, Mr Hearty, do you?" Quick as thought, he replied, "No, sir, it's either a *berolinensis* or a *helcogenes*, but it's certainly not a *choleræ*." There is an effective counter-ploy which was first demonstrated by Xavier Odoreida, elder brother of the famous Old Wykehamist. Xavvy spent three years as bacteriologist at St Rhoea's. In the above case his counter ploy would have run something like this: "I agree with you, Mr Hearty, but if it's not a *choleræ* I never bother to take it any further." These examples will show that Labmanship has its own problems and can legitimately claim to be regarded as a specialised branch of Medical Lifemanship. I have felt for some time that there is room for a Section of Lifemanship at the Royal Society of Medicine, and I herewith invite any Fellows interested to communicate with me on the matter.

Aphorism of the Week

We stand on our fathers' shoulders, but our children tread on our corns.

Letters to the Editor

METHONIUM COMPOUNDS IN HIGH BLOOD-PRESSURE

SIR,—The statement has been made several times recently that the benefits to be derived from methonium salts in hypertension are uncertain, and that there is no strong indication that their introduction has changed the outlook for high blood pressure patients. Experience here does not lead to this conclusion, and I have come to regard the benefits of effective methonium therapy in high blood pressure as of a different and higher order from those ordinarily obtainable by other methods. Differences in the opinions held about the treatment seem to depend partly on the method of using the drugs.

In a large hypertension clinic we have seen the results of thiocyanate,[1] salt free diets, and sympathectomy in the treatment of high blood pressure. Recently with Dr Oliver Chapman a study has been made of some of the newer veratrum preparations. All these measures produce some excellent results, but many failures. With pentamethonium and hexamethonium salts, however, it is possible to obtain in almost all patients a much more effective control over blood pressure levels than has hitherto been practicable, and the relief of clinical manifestations secondary to the high blood pressure is correspondingly greater.

In successive collaboration with Dr P A Restall[2] and Dr K S Alstad (unpublished) the effects of these substances have now been studied in 130 patients with substantial hypertension of various ætiology, and 34 patients with severe hypertension, including 9 with malignant hypertension, have been treated for one to twelve months, with no deaths. The outspoken clinical improvements referred to in previous communications have been maintained.

Our early results were obtained by subcutaneous injections. We noted subsequently that authors reporting the effects of oral administration were less satisfied with their results than we had been with ours; therefore we continued mainly to employ subcutaneous injection.

One factor which, in some instances, may have limited the degree of benefit obtained, whatever the method of administration, is that there has not been sufficient recognition of the tolerance which develops with continued administration of pentamethonium or hexamethonium salts; thus an initial dose of 15 mg subcutaneously may produce as great an effect as a dose of 80–200 mg administered by the same route after two or three months of continued treatment. Hence, if a fixed routine dose is employed, the hypotensive effect of one and the same dose may prove dangerous in the early stages and ineffective later.

Recently Dr Kilpatrick and I have studied the effects of oral administration in a number of patients who, having developed the full degree of tolerance to subcutaneous injections of methonium salts, have had the desired amount of blood pressure reduction for several months without further increase in dose. In such patients the effective oral dose is high, but some patients remain sufficiently sensitive to have a sufficient degree of blood pressure reduction with oral administration, even when full tolerance is established. Several patients, however, could not take doses of hexamethonium bromide large enough to reduce the blood pressure, because of the prior onset of nausea, diarrhœa, or vomiting. Other patients required an oral dose of 3000 mg of the drug to reduce the blood pressure. Such a dose is of the order of 20 times the effective subcutaneous dose and should not be administered outside hospital, because an alteration in the rate of alimentary absorption could be dangerous, and delayed absorption is not unusual

---

[1] Alstad K S *Brit Heart J* 1949 11, 249

N Z *med J* 1950 49 206

Patients who have not been treated previously with methonium salts respond to much smaller oral doses for example, 500 mg commonly induces a fall of blood-pressure in the upright posture It would appear, therefore, that tolerance develops in the course of oral administration as well as with subcutaneous dosage With oral administration the drug action is more capricious even under rigidly controlled conditions Therefore we feel that continued effective oral therapy is sometimes impracticable, however, continued treatment by subcutaneous injection is almost always possible

In reducing blood pressure levels with methonium compounds there is more than the usual need to adjust the treatment to the individual response of the patient Without frequent observation in the initial stages it is only by chance that the patient will escape discomfort or danger on the one hand, and ineffectiveness on the other It is, however, my experience that these drugs can be used in such a way that they give unmistakable relief to a considerable proportion of hypertensive patients, and, after a period of observation in hospital, outpatient care presents no difficulty

BROMISM ON LOW-SALT DIETS

Sir,—My attention has recently been drawn to a danger associated with the use of low salt diets

A patient who had previously been in hospital with severe hypertension and left ventricular failure and who had been sent home on a low-sodium diet was readmitted in a state of mental confusion His blood-bromide level was found to be 360 mg per 100 ml. (expressed as NaBr) He had been treated with moderate doses of ammonium bromide by his own doctor His renal function was normal.

It became evident that doses of bromide which would be well tolerated by people on normal diets might lead to bromide retention in patients on a low salt intake for the body's excretory mechanisms cannot distinguish between the chloride and bromide ions

There were in the wards at that time four patients with hypertension who were being treated with hexamethonium bromide by mouth and who were also on a low-salt diet The blood bromide level was found to be raised in all four—ranging from 120 to 300 mg per 100 ml. (as NaBr)

This problem is being investigated further, but it is clear that the salt intake of patients receiving hexamethonium bromide over long periods should not be rigorously reduced and that a watch should be kept on the blood bromide level.

University College Hospital,
London.

M L Rosenheim

Sir,—Correspondents have emphasised the danger of indiscriminately using the methonium halides[1] In concurring with this opinion, we would draw attention to the occasional development of dangerously high levels of blood-bromide after prolonged administration of the bromide salts of methonium. Bromine comprises some 44% by weight of the molecule of hexamethonium bromide and an even higher percentage of the penta methonium salt Therapy with these compounds therefore involves administering a substantial dose of bromine, especially since, in our experience, tolerance seems to become established, necessitating a progressive increase in dosage. Unfortunately an iodide preparation for oral use is not at present available.

Goodman and Gilman[2] place the toxic level of blood bromide at 150–200 mg per 100 ml., and add that if unexplained mental or neurological symptoms are found in association with a blood level of even 75–100 mg per 100 ml bromide intoxication may be suspected as the cause

Amongst a group of six patients receiving methonium bromides, two complained of severe drowsiness and were found to have blood-bromide figures within the toxic range, the readings in the other four cases all being less than 75 mg per 100 ml. The most severe symptoms were in a man, aged 47, with malignant hypertension and cardiac failure Routine treatment of the cardiac failure included salt restriction, together with the administration of digitalis and mersalyl An intramuscular, and later an oral, preparation of pentamethonium bromide was given, in gradually increasing dosage, over a period of 7 weeks before toxic symptoms developed. He was then taking 3 g daily the blood-bromide level being 175 mg per 100 ml. Restoration of a normal salt intake, supplemented by 3 g sodium chloride daily, rapidly abolished the drowsiness, and within a fortnight the blood-bromide had fallen to 125 mg per 100 ml. although during the same period it had been necessary to increase the dosage of pentamethonium bromide to 6 g daily

It is recognised that those using salt sparingly are unduly susceptible to bromide intoxication It would therefore appear that, in the treatment of cardiac failure secondary to hypertension, severe restriction of sodium-chloride intake should be avoided if methonium bromides are to be used, and we would again stress the necessity for careful medical supervision while these drugs are being administered

SEASONAL INCIDENCE OF CONGENITAL MALFORMATIONS

Sir,—The article by Professor McKeown and Dr Record (Jan 27) illustrates two forms of statistical convention which, I suggest, would be undesirable anywhere, and are particularly out of place in a non specialist journal

The first is the lavish use of numbers like 0 70 ± 0 31, with no indication as to what the 0 31 means. I assume it is the standard error, or some multiple of it such as probable error, but whatever it is should have been stated And what are we to make of the *observed* malformation rate (table VIII) of 2 77 ± 0 76%—unless it be the authors' estimate of their error in dividing 13 by 470? No doubt, however, it is intended to be some measure of the uncertainty range of the true rate But what measure?

The other bad habit is the description of findings as "significant" or "not significant" without any indication of the level of significance taken as critical, as it is, the designations are useless The proper way is to state the probability of the result occurring by chance, and furthermore to state or imply what probability hypothesis has been assumed. The responsibility is then on the reader to make up his mind whether to regard the result as true or as a chance effect If the scientist wishes to help the reader to decide, as his expert knowledge may very well entitle him to do, he should do so in the form of an opinion, but he ought not to hide behind magic words like "significant"

A degree of significance is simply a probability, calculated on a certain assumption No matter how large or small it is, by itself it tells us absolutely nothing about the truth of the proposition to which it refers It is equivalent to saying that something is as long as a piece of string A degree of significance means nothing until it is compared with another quantity of like kind —i e, another probability The other probability is the piece of string in the case, and we must know how big it is before the comparison can give any information.

---

[1] Hillis B R Kelly J C C *Lancet* 1950 ii 5[illegible]0 Ball J D *Ibid* p 650

[2] Goodman, L Gilman A. Pharmacological Basis of Therapeutics New York 1941 p 161

Broadly speaking, the counter probabilities are of two kinds a priori probabilities, and profit loss expectations For example, if, before trial, we regard a proposition as equally likely to be true or false, a significance of just less than 0 5 must decide us in favour of "true," *provided* we know we shall gain as much if we are right as we shall lose if we are wrong It is unfortunate that the counter probabilities usually depend upon subjective judgment, with all the uncertainty which that implies But it is surely better that the skeleton should sit visibly at the scientific feast than be hidden away in the cupboard

Psychological Laboratory
Cambridge

W E HICK

SIR,—Your leading article of Jan 27 on the "Ætiology of Anencephalus" indicates that several factors may be at work in the causation of this, as of other, congenital abnormalities It may be that heredity is of importance, and possibly the other influences only operate when a suitable gene is present With regard to the other factors I should like to add the following comments

First, Duraiswami [1] has shown that insulin hypoglycæmia may be *one of the causes of fœtal abnormalities in chick* embryos It seems reasonable to infer from this that vomiting in early pregnancy, anorexia, and mild starvation may be important factors in the causation of abnormality in the human fœtus

Secondly, with this in mind it is interesting to study the data obtained by McKeown and Record [2] Their table XLII *(disability during pregnancy) contains these figures*

—	Malformation in fœtus					Controls
	Anencephalus	Spina bifida	Hydrocephalus	Others	Total	
Number of cases studied	305	309	118	23	755	742
Cases with vomiting						
Number	28	20	3	1	52	37
Percentage	9 2	6 5	2 5	4 3	6 9	5

In other words, among the mothers of anencephalic fœtuses vomiting was nearly twice as common as among mothers of normal children

Now comes the startling discovery by Professor McKeown and Dr Record that stillbirths due to anencephalus are considerably more common in December than in June, and your comment that this may be due to infection, diet, allergy, or abnormal activity during spring cleaning I was about to suggest that Lenten fasting might be another possibility, returning to the theme of hypoglycæmia But a study of McKeown and Record's paper (*Lancet*, Jan 27) shows *that the anencephalics were not born at full term but had been conceived in April, May, and June, and there was still* a high rate for July, August, and September conceptions *Even the most extreme date for Easter can hardly bring* Lent into this period, though the spring cleaning may be delayed for several months

Another line of attack, as you mention, has been on the effect of lack of vitamins, particularly vitamin A There should be enough vitamin A in our diet now that National Butter and Special Margarine are universally provided, but some pregnant women have a dislike for fat and may thus become deficient Of course there are other sources of vitamin A, such as eggs and milk, while carrots provide the precursor carotene Any gardener knows *that April to June is the one period of the year* when fresh carrots are unobtainable The old ones have been *eaten* or have withered and rotted, and the young ones are not yet grown It would be interesting to have the views of expert dietitians on the seasonal variations of the vitamins in our diet, and also to have any information that Professor McKeown and Dr Record can provide about the diets of the mothers of anencephalic fœtuses

Until more is known about these factors it would seem to be good antenatal pediatric practice to pay more attention to the rapid correction of vomiting in pregnancy and to the provision of adequate supplies of vitamins from the earliest possible moment in pregnancy

OCCUPATIONAL THERAPY

SIR,—*I agree* with much *that* Mr *Krauss (Jan 20) has to say* Perhaps in my letter (Dec 30) I failed to make my point clear The crafts I had in mind restore function and by arousing interest stimulate mental recovery They involve the extensive use *of machine tools*

For many patients I see no value in a "work environment" *doing economically unproductive machine* work In many cases they are not initially fit for this work Many workers *recovering from sickness or injury* need no specifically industrial rehabilitation they merely need *rehabilitation My plea is for a wider view* Craftwork properly organised has much to offer At Farnham Park in the *Slough Industrial* Health Service an example of this type of work may be seen

Farnham Royal Bucks

M E M HERFORD

APPLICATION OF PSYCHOLOGY TO DERMATOLOGY

SIR,—*I read with great interest and profit* the article of Jan 13 by Dr MacKenna and Dr Macalpine

The most controversial section of the paper, it seems to me, is that which seeks to establish a clear distinction between the mechanisms involved in psychoneurotic and psychosomatic symptom formation

> "*Somatic manifestations such as skin disease are mostly affect equivalents'—they may be a disguised discharge of* anxiety, fear, rage, or any other simple affect'

This statement, if true, would involve a reassessment of the concepts of emotion and its conative component which I accept at present This concept, which was elaborated by Rivers [1] and others, states that emotion accompanies an impulse to action, and that so long as free expression is given to the impulse emotion remains minimal Should the direct pathway of expression be denied to the impulse, then emotion will increase to an intensity which inspires the individual to seek alternative methods of satisfying the impulse This suggests that emotion does not occur per se but is always the accompaniment of a drive or impulse to action I submit that the attempt to find *alternative* paths of expressing drive is *the mechanism* behind symptom *formation*, and *not an alternative path of emotional* expression

Conscious suppression of emotion because of social *situation* or *out* of regard for the feelings of others is an adaptation which is called for daily in each of our lives If, as Dr MacKenna and Dr Macalpine suggest, such suppression of emotion could give rise to psychosomatic disturbance, one would expect this to be much commoner than it is But if one takes the view that it is drive that is denied expression and that seeks an alternative through symptom formation, then the psychosomatic symptom may have the same significance as the compulsive acts of the obsessional, *the tics*, and the conversion symptoms of hysteria

The example quoted in *the* article as a *simple affect* equivalent is of a woman, aged 45 who suffered from *blepharitis conjunctivitis*, and itching around the eyes It is suggested that this was due to the fact that, when her father had died some nine months previously, she had out of consideration for her mother bottled up her feelings of grief and that this suppressed affect was then discharged through some psychosomatic mechanism in the symptoms of which she complained

---

[1] Duraiswami, P K *Brit med J* 1950 ii 384

[2] McKeown T Record R G *Brit J soc Med* 1949 3, 183

[1] Rivers W H R Instinct and the Unconscious Cambridge 1920

In order fully to understand the symptom and the total situation of which it is a part, is it not necessary to understand what drive, impulse, or wish was being denied expression, and was so producing a pressure of painful emotion ? May not the symptoms around the eyes be an attempt to find an alternative channel for expressing the drive or wish rather than the emotion ?

Freud in his classical paper, Mourning and Melancholia,[2] has suggested that mourning involves the withdrawal of all libido from the love object and its gradual detachment and redistribution In this process some individuals may direct, at least temporarily, some of the displaced libido on themselves. Since all love involves ambivalence, the hostile component may thus be self-directed and in this way involve psychosomatic manifestations I am not of course suggesting this type of mechanism for the case described, but offer it as evidence of the deeper interpretations involving libido rather than affect which might be applicable

The fact that such symptoms as those described may be cured by abreaction does not affect the issue, since it is the painful intensity of the emotion which makes the individual seek to express libido through alternative channels The painful affect, having been as it were artificially tapped and discharged, no longer serves as an impetus and the symptom may disappear If the abreaction extends over that time during which the deflected drive is operating, then a good result may be obtained , but if the drive is persistent, then one must expect a further accumulation of painful affect The bearing of this on relapse is obvious

Dr MacKenna and Dr Macalpine refer to other examples of the miracle cure in the early stages of psychological investigation and therapy Such dramatic improvements of symptom occur also in the psychoneuroses during the early stages of treatment, and may also involve abreaction Others occur after the redistribution of libido accompanying the formation of the transference , and still others may be due to defence mechanisms, such as the flight into health Whatever they may be, it is my contention that they all involve redistribution of libido rather than the discharge of affect alone

All this bears profoundly on that part of the paper which puts forward the view that psychosomatic symptoms have no meaning and no psychic content I have found that this is not so in the perplexing symptom variation found in patients suffering from the eczema asthma complex In treating such patients I have tried to relate the current psychic situation to the physical symptoms In a number of patients I found that I could predict with a significant degree of accuracy the variation that would take place I thought at first that this was related to certain complex formations , but I later revised this view, and I came to the conclusion that when the patient was expressing himself freely and with pleasure in the analysis, eczema was the prominent symptom, but that when defences were operating and the patient was struggling painfully through them, then asthma was the prominent symptom This has suggested to me that eczema represents an outgoing of libido and asthma a retention or bottling up of libido

I have quoted this particular example because Dr MacKenna and Dr Macalpine refer to infantile eczema, and suggest that the only psychological interpretation must be a correlation with adult types of conflict It may be significant that infantile eczema occurs during that period of life when in fact there is little impediment to the free expression of libido, and asthma supervenes when the child is old enough to have developed conflicts involving the repression of libido

Although in this letter I may have shown a bias towards the psycho analytical approach to psychosomatic disease, I am convinced that the next advance in this field will come neither from the clinician nor from the psychiatrist but from the neurophysiologist I feel it is essential that understanding of the neurophysiological mechanisms involved in psychosomatic symptom formation should be greatly extended to form a firm structure on which theory may be based Such a structure would serve as a framework for the sceptical clinician and as a bridle for the enthusiastic psychiatrist I see a real danger that in the study of psychosomatic medicine we may establish a top heavy load of theoretical and facile explanation unfounded on accurate knowledge of the neurophysiological mechanisms involved

I have concentrated on those parts of the paper which are, as the authors say, controversial , but I agree with a great part of the paper, which has lessened my ignorance of the subject

DESMOND IRWIN

ACUTE OBSTRUCTIVE LARYNGOTRACHEITIS

SIR —We have been interested to read the article by Dr Forfar, Dr Keay, and Dr Thomson, in your issue of Jan 27 As these writers suggest, the condition is probably much more common than the reported cases suggest

At this hospital there have been 26 cases in the last three years, one of which, a baby of six months, was admitted a year later with a second attack 7 of the cases were under one year of age, 8 between one and two years, 8 between two and five years, and 3 over five years Most of these cases were admitted with a diagnosis of laryngeal diphtheria As regards severity, 10 of the cases were regarded as severe, and the remainder either moderate or mild and not causing any anxiety as to the outcome Of the severe cases, 1 died on admission and 2 required tracheotomy but recovered An autopsy on the child who died was carried out by Dr J Hart-Mercer, who commented that, although the ulcerative condition was limited to the larynx, the similarity to the acute laryngotracheitis of infants was very marked and there was considerable destruction of the mucous and submucous tissues , and, in addition, *Staphylococcus pyogenes* and *Streptococcus viridans* were cultured from the larynx

Hæmolytic streptococci were found in 4 other cases, 2 of which were the cases requiring tracheotomy , *Staph pyogenes* was found in 2 , and the remainder gave negative pharyngeal swabs One child two months old, who had a moderately severe attack continued to have stridor for a month after recovery, and bronchoscopy showed a large granulating area in the trachea which eventually resolved without sequelæ

Treatment of most of these cases previously was by steam, antitoxin, penicillin, and sulpha drugs , but 5 recent cases have had chloramphenicol and 1 'Aureomycin,' and all seemed to respond much quicker than formerly The cases requiring tracheotomy were a child of eleven months and an older child of nine years , and both were thought unlikely to survive without interference In both instances the subsequent course was stormy and associated with further obstructive spasms due to necrotic tissue and secretions

One wonders whether a similar condition may not occasionally occur in adults A soldier, aged eighteen, was admitted in 1947 in extreme distress from laryngeal obstruction, which had commenced suddenly with pain on swallowing, and talking about eight hours previously and required tracheotomy soon after admission Swabs from pharynx and tracheotomy wound were negative The condition, which gradually cleared, was associated with a temperature of 101 8°F and considerable induration of the cellular tissues of the neck

SCHOLARSHIPS AT THE LONDON SCHOOL OF HYGIENE

Sir,—In recognition of the services of Sir George Elliston, who has just demitted office as its chairman after eleven years' tenure, the board of management of the London School of Hygiene and Tropical Medicine have decided to offer two scholarships of £150 each, with free tuition, for students taking its course for the diploma in public health commencing in October, 1951 Official intimation will be found in the advertisement columns These are additional to the Bygott scholarships, awarded by the University of London, also tenable at this school, about which official notification will appear later

The board hope that the Elliston scholars will eventually join the preventive services in the United Kingdom, the number of recruits to which has been seriously reduced by the discrepancy existing between the emoluments offered and those obtainable now in other branches of the medical profession We hope that many more of the medical officers of health of the future will become the pivotal points of the medical services of their areas All thinking people deplore the increasing tendency for each section—domiciliary, hospital and preventive—to develop and function as separate entities The medical officer of health with the proper outlook and background should, we think, be the coordinator , this implies a very adequate clinical training, and we hope that men of good quality will give careful consideration to adopting community health as their career

The modern course for the D P H is much more a cultural discipline than a technical training, and there are few young medicals who would not derive great benefit from it whatever their ultimate aim may be

POLIOMYELITIS AND POLIOENCEPHALITIS WITH OPSOCLONIA FOLLOWING APPENDICECTOMY

Sir,—Dr Warren, in his interesting paper of Jan 27, remarks "The association [of poliomyelitis] with appendicectomy has only rarely been reported " Admitting the possibility and the analogous instances described, I would submit that the association is so rare that the diagnosis should be most carefully considered On the other hand, the history of " appendicular colic " followed by mental confusion and symmetrical ascending paralysis is typical of acute porphyria

This may be appreciated if the case be compared with Kinnier Wilson's description,[1] which could be read as an accurate account of Dr Warren's case, including the following features which are most unusual in poliomyelitis (1) considerable delirium at the onset (of a spinal type) with absence of pain in muscles, which were flaccid next day , (2) retention of urine at an early stage [2], (3) ascending flaccid paralysis of symmetrical distribution , (4) pyrexia continuing for five to six weeks , and (5) an encephalitic episode with convulsions five weeks after the onset I do not deny that each of these features has been described in poliomyelitis , but all are rare, whereas each is mentioned by Kinnier Wilson as a feature of acute porphyria

The only feature of the report which is against a diagnosis of porphyria is the cerebrospinal fluid It is regretted that the pressure, type of leucocyte, and number of erythrocytes present are not recorded The figures presented are compatible with poliomyelitis, though at the stage described one would have expected a greater pleocytosis and a lower protein I should like to be reassured of the absence of blood contamination Furthermore, there is no mention of inflammatory or obstructive pathology in the appendix , " a long kinked retrocæcal appendix " is a poor basis for diagnosing appendicular colic

ADRENOCORTICOTROPIC ACTIVITY OF BLOOD PLASMA EXTRACTS

Sir,—The article of Dec 2 by Miss Trowbella and myself contains an ambiguity In the section " Preparation of Extract " it is stated

> " The plasma was taken off and added to 4 volumes of acid acetone, prepared by adding 25 ml of analytically pure hydrochloric acid to 975 ml of redistilled acetone The resulting precipitate was allowed to stand at room temperature for eight hours, vigorously shaken at intervals, and then centrifuged The supernatant fluid was taken off, 1 ml of saturated sodium chloride solution was added and the concentration of acetone was brought to 94% "

The last sentence should read " The precipitate was discarded, and the acetone concentration of the supernatant fluid was brought to 94% after adding 1 ml. of saturated sodium chloride solution "

PULMONARY HYPERTENSION IN MITRAL STENOSIS

Sir,—Some clinical observations appear to support Dr Dornhorst's contention, in his letter of Jan 6, that the increase in heart rate during exercise may influence the pulmonary artery pressure in mitral stenosis Thus Gallavardin [1] in 1921 commented on the apparent precipitation of pulmonary œdema when certain patients with tight mitral stenosis developed a tachycardia More recently Harken et al [2] observed the ill effects of a tachycardia developing during operations on the mitral valve and attributed this in part to shortening of the diastolic time We also have noted that a tachycardia of emotional origin, such as may occur the night before operation, may apparently precipitate pulmonary œdema

However, some experimental evidence and our incomplete knowledge of factors affecting the circulation make it doubtful whether simple mathematical calculations can legitimately be applied to this problem If the right side of the heart can be assumed to be analogous to the left, it has been shown that atropine induced cardiac acceleration in normal subjects is associated with a fall in right auricular pressure despite a rise in cardiac output [3] Furthermore the effect of digoxin on the cardiac output and venous pressure in heart failure due to mitral stenosis does not appear to bear any relation to the degree of cardiac slowing achieved, nor does atropine acceleration following digoxin therapy reduce the cardiac output or increase the venous congestion

Thus despite theoretical considerations there is indirect evidence that tachycardia per se may not necessarily be a major factor in increasing the pulmonary artery pressure in mitral stenosis So far as I know, direct evidence on this point has not yet been reported, but an unpublished observation in this country showed that on exercise, when there was a marked tachycardia but no increase in cardiac output, the pulmonary "capillary"-pressure rose slightly, indicating a rise in left auricular pressure, whilst there was a conspicuous increase in the pulmonary artery/pulmonary "capillary" gradient, indicating increased pulmonary vascular resistance

CORONARY DISEASE AND MODERN STRESS

SIR,—Reference has been made by Professor Platt (Jan 6) and by Dr Stewart (Jan 27) to an observation in the Registrar General's Decennial Supplement for 1931, which was based upon study of the death certificates of men between the ages of 20 and 65 during the years 1930–32 This was to the effect that, whereas among men whose social conditions are most favourable degenerative heart-disease tends to express itself as angina pectoris or coronary disease, at the other end of the scale it tends to take forms described on death certificates as myocardial or cardiovascular degeneration

It is becoming a convenient expedient today to explain away unpleasant things in vital statistics—such as the rising death-rates from bronchogenic cancer, leukæmia, or mechanical suffocation of infants—by faults and changing fashions in certification, although when a death rate is falling it is readily accepted as authentic It is also possible to resort at once to this "explanation" when death statistics throw up something surprising and difficult of explanation, but if carried to its logical conclusion this would mean that vital statistics of separate causes of death are a rather futile study

In this particular instance it would seem to be more difficult to accept that explanation than to accept the figures at their face value I have often been accused of having too high an opinion of the intelligence of certifying medical practitioners, but I have never credited them with superhuman ingenuity To suppose that their vagaries in diagnosis and certification were so ordered in irregularity as to produce the figures below seems to me rather like that tiresome idea of a million monkeys producing by accident the Book of Job on their million typewriters

Dr Stewart prefers to think that doctors knew something about angina pectoris even in country and industrial practices in 1930–32, and he leans to the idea that the explanation lay in the differing proportions of men who were afflicted with anxiety to better themselves, or the world generally, at different levels in the social scale That might perhaps account for the social class gradient of the coronary myocardial ratio, but it will hardly explain the curious differences in this ratio between occupations whose outstanding contrast was in the physical nature of the work done rather than in the mental outlook of the workers The amount of physical energy expended in an occupation has not been considered as a factor of importance in determining the type of heart-failure which terminates life, although that would be an obvious reason for the class gradient Broadly, the social grouping used in 1930–32 was correlated in a negative way with calories expended in physical work, and if that happened to be an important factor in determining the coronary-myocardial ratio it would explain the class gradient just as well as the mental stress hypothesis At that stage of our civilisation at least, mental stress and a sedentary life tended to go together, and the second might be even more important than the first in its effect on the coronary arteries

The figures below have been taken from table 4A of the report referred to, as anyone could do who, following Professor Platt's advice, took it to bed with him and applied pencil, paper, and simple arithmetic I have tried to arrange some of the large occupations into five groups in descending order of the physical activity I think they involve, keeping apart another two groups of rural workers for separate comparison because they have low death rates from every cause

Group nos	Occupation groups	Total coronary and myocardial deaths	Coronary % of total	S.M R at 20–65	
				Cerebral hæmorrhage	Nephritis
4 48 57 87	General and dock labourers navvies, coal hewers	3495	14 8	103	100
16–19 23 44, 45	Furnacemen smiths boiler-makers bricklayers, builders labourers	1175	18 7	101	86
20 42 43 58 64 65	Metal machinists printers compositors retail salesmen potmen sorters	643	25 3	106	87
56 63	Motor drivers commercial travellers	512	36 3	79	87
67 68 74 82 83	Teachers, clerks bankers administrative officials	1242	38 6	101	103
3	Agricultural labourers	550	14 3	59	58
1	Farmers and their relatives	493	22 6	106	87

The standardised mortality ratio (S M.R) for total heart-disease was above average (114) for the general labourer group, but was very low (68) for agricultural labourers Nevertheless, in both groups coronary disease formed one seventh of the total deaths from coronary and myocardial disease combined The proportion increased steadily with diminishing physical activity to about two fifths in the most sedentary group Farmers and their relatives gave a proportion between those for the second and third groups, which is reasonable Neither cerebral hæmorrhage nor nephritis showed differences in mortality comparable with the progression of the coronary-myocardial ratio

It is to be hoped that the occupational mortality statistics for years around the census of 1951, based as they will be upon the new International Classification of Diseases which attempts to differentiate hypertensive disease, will throw further light on this problem

PERCY STOCKS

PROTRUDED INTERVERTEBAL DISCS

SIR,—May I warmly endorse Dr Jefferson's plea (Jan 20) for conservative treatment of laterally placed cervical disc lesions? Since spontaneous cure is nearly always established at the end of three to four months in 5th, 6th, and 7th root compression, and in six months at the 8th root, operation is very seldom indicated unless the spinal cord is compressed as well

Curiously enough, Dr Jefferson does not mention the swiftest conservative measure of all, which is of course manipulative reduction In the stage where there is scapular pain only (what used to be called "fibrositis") the displacement is slight, and one session often suffices, when root-pressure has supervened reduction is more difficult, but is often still possible For the past six years manipulation during traction has been the method of choice in our physical medicine department, traction in recumbency, head suspension, a collar, or waiting for spontaneous cure are reserved according to circumstances, for displacements irreducible by manual means

I was most interested to read the paper by Mr Floyd and Dr Silver, also in your issue of Jan 20 In my view, relaxation of the sacrospinalis muscle as trunk flexion proceeds is the mechanism for preventing lumbar-disc lesions It must not be forgotten that the first action of the sacrospinalis muscle is to approximate the vertebræ, only when this slack has been taken up can the muscle act as an extensor Compression of the joint while it is held in the kyphotic position is the usual cause of retropulsion of part of the disc, and the relaxation of the sacrospinalis muscle that Mr Floyd and Dr Silver describe diminishes this possibility

Mr Charnley's article (Jan 27) emphasising the importance of estimating straight leg raising is to be welcomed The range of this movement is proportionate to the pressure exerted on the nerve root, except in cases where pressure atrophy is taking place

During attempted manipulative reduction of a lumbar displacement causing sciatica, straight leg raising is a most sensitive test, varying from moment to moment as the loose fragment moves We therefore use it as an immediate measure of the success of each different manipulation A particular technique is tried, and the effect on the range of straight leg raising is estimated at once In this way, so long as the patient is not anæsthetised, the method best suited to him can quickly be discovered

An interesting phenomenon that we often notice is the appearance of a painful arc on straight leg-raising when reduction is almost complete This I interpret as the root catching against so small a protrusion that it glides over The main virtue of straight leg raising is that it clearly indicates the size of the protrusion at any one instant

St. Thomas's Hospital,
London S.E 1
JAMES CYRIAX

SIR,—In last week's article by Mr Burns and Mr Young one reads that low back pain and sciatica are probably "part of the price we pay for our upright posture" This phrase is handed on from author to author It seems to me that we pay with these ailments for our civilisation Has one found these disorders in African negroes, Australian aborigines, or Polynesians? Are these disc accidents not a sequel of our wrong posture, our wrong way of using our body, and our lost bodysense? Are these disc operations not another example of combating the smoke and leaving the fire burning?

London, W C 1
E F MEYER

⁂ A corrigendum for the paper by Mr Burns and Mr Young appears on p 358

TUBERCULOSIS FIGURES

SIR,—Your annotation of Jan 6, and numerous articles and letters in the medical and lay press, rightly focus attention on the apparent increase in the morbidity of pulmonary tuberculosis The facts give cause for serious anxiety, and the Glasgow figures, backed by a corresponding increase in mortality rate, are alarming None the less it is essential for a full appreciation of the position and for the initiation of steps to bring tuberculosis under control that the notification figures should have some degree of accuracy, this, at present, is plainly not the case

There is a wide divergence of opinion as to what cases of tuberculous infection should, and what cases should not, be notified Apart from the clear cut instance of active pulmonary tuberculosis with tubercle bacilli demonstrable in the sputum, the variation in procedure is formidable The diagnosis of erythema nodosum (a condition now recognised as usually following closely on a primary tuberculous infection) should lead to an intensive search for the original source of infection The necessity for this procedure is one of the chief arguments for notifying the disease, yet the majority of such cases are not notified Similarly, cases of pleural effusion are invariably notified by some, and rarely or never by others Again, should action be taken on the diagnosis of a minimal tuberculous lesion of the lung found to be healing without treatment?

The anomalies are further underlined by the official figures for pulmonary tuberculosis in children under 15 years of age The 1948 figures for Glasgow, Leeds, and Bristol, kindly supplied to me by the medical officers of health, read 510, 27, and 71 This wide variation cannot be wholly explained by inequalities in total population, in social condition, in opportunity for infection or in degree of immunity The discrepancies must largely be due to a difference in interpretation of the regulations

In 1945 the Joint Tuberculosis Council went some way towards improving the position by advising the Minister of Health that notification should be a two stage procedure of (1) intimation, followed if necessary by (2) full notification Five years have elapsed with no apparent result, and the time is ripe for reconsideration In formulating new regulations, whether or not "intimation" is accepted, some lead should be given as to the criteria for notifying such conditions as intrathoracic tuberculosis in children, pleural effusions, and minimal tuberculous lesions of the lung

Review and subsequent modification of the notification system is essential if the morbidity figures are to provide adequate data for planning the attack on tuberculous disease

King's Lynn
G F BARRAS

VACCINATION AGAINST SMALLPOX

SIR,—Dr Dixon (Jan 20) has already disposed of several of the arguments against vaccination put forward by Dr Killick Millard in his article of Jan 13 There are a number of other fallacies in this article, but it is scarcely necessary to discuss these since Dr Millard himself invalidates his entire thesis when he writes "Incidentally I am all in favour of everyone who visits the East being efficiently protected by recent vaccination "

A little later he quotes the example of the recent outbreak of virulent smallpox at Glasgow, initiated by the arrival of a "well vaccinated" Asian seaman from the Far East I believe that in fact all the recent outbreaks in Britain have been originated by persons arriving from the East If Dr Millard is going to have all such travellers vaccinated, then, according to his own argument, he is going to increase the number of undetected cases and hence the number of outbreaks The only way in which such occurrences could be prevented would be to subject every arrival from the East to medical examination, and then to place in quarantine all those with slightly suspicious symptoms even if the disease did not appear to be smallpox

Arlesheim
Switzerland
A M WOOLMAN

SIR,—In his article Dr Killick Millard says "Dr Stallybrass in the *Medical Officer* of July 29 last thinks that the danger of spread from unrecognised cases in unvaccinated subjects counterbalances my argument as to the spread from unrecognised cases in the vaccinated" In the interests of accuracy, may I observe that this suggestion emanated from me (*Medical Officer*, July 8, 1950)

I recall that correspondence for another reason In his final letter (*Medical Officer*, Aug 12) Dr Millard admitted that too little attention had been given to the relative danger of smallpox in vaccinated and unvaccinated subjects, and that, as his argument was based merely on personal belief, he proposed to devote some time to collecting definite data on the question It is disappointing, therefore, to note that he makes no further reference to this projected research Certainly his latest article contains few novel aspects, it consists in a repetition of the same old selected facts and biased evidence It does, however, show one new feature of great promise He concludes that, since he cannot agree with any view which differs from his own, he can only leave it for others to decide

More serious is Dr Millard's propagation of his views in the lay press by an article under his name which appeared about the same time in a popular journal The issemination of these views can have nothing but a etrimental effect on the level of herd immunity, the nportance of which was emphasised, among other oints, by Dr Dixon in your issue of Jan. 20.

ALARMING NAMES FOR HOSPITALS

SIR,—I endorse the remarks in your annotation of ec 30. If anyone remains doubtful of the layman's eaction to these ill conceived titles, let him see the faces f his fellow passengers when, on a number 14 bus, he sks clearly for his ticket to " the Cancer Hospital."

St Bartholomew's Hospital
London E C 1
GEORGE H DU BOULAY

ACQUIRED IDIOSYNCRASY TO SODIUM *p*-AMINOSALICYLATE

SIR,—The case of P.A.S. sensitivity with jaundice eported by Dr Little (Jan 27) is an interesting contribuion to this subject, but we must disagree with his onclusion that the blood-P.A.S. level may be presumed o rise steeply in such cases. Reference to our own case eport[1] will show that the blood level on the first day f the reaction was scarcely any higher than during the irst week of treatment, and was actually lower than n the preceding week. We would like to emphasise his point in case an erroneous impression is gained that repeated blood estimations will enable the physician to foresee and prevent such a reaction.

Whether the total dose of the drug at the time of onset of the reaction is the deciding factor in determining its severity is also debatable. We have had a case which developed a P.A.S. sensitivity reaction much less severe than the one we reported, in which the total dosage was 760 g. over a period of 38 days. It is now our practice to discontinue P.A.S. *at once* if a patient taking this drug shows a sudden rise of temperature, which is usually if not always the first sign of idiosyncrasy. In all the reported cases of severe allergic reactions to P.A.S., treatment with the drug was continued for some days after the onset of pyrexia, and in our opinion this is probably more important than the total dose in determining the severity of the reaction.

TREATMENT OF THE AGED SICK

SIR,—Many of those concerned with the care of the aged sick must have been compelled by the article (Jan 20) by Lord Amulree and his colleagues to make comparisons, and to look again for new and more hopeful lines of approach. As we are constantly faced with the economic aspect, it would be interesting to know the cost, in medical and nursing man-power, of achieving the results described.

As a comparison, in one hospital group with more than 100 aged sick cases, it is found that, on a basis of 1 trained nurse to more than 20 cases, and of 1 untrained nurse to more than 3 cases, it does not seem possible to achieve the turnover quoted in the article. But of course the other factors mentioned play a large part in diminishing the discharge rate.

Many provincial hospitals must be having similar difficulties, perhaps some peculiar to their own locality. In the Eastbourne area for example, the percentage of the population in 1947 aged 65 and over was 16.7, whereas the figure for England and Wales was 10.9. One difficulty must, however, be common to all—namely, the problem of senile mental changes. Surprisingly, Lord Amulree and his colleagues make no reference to senile mental changes as a reason for a patient being confined to bed.

LEUCOCYTE-COUNTS IN THIOURACIL MEDICATION

SIR,—Many clinics have satisfied themselves that symptoms give an adequate warning of the need for action against agranulocytosis in thiouracil treatment. The case described last week by Dr Holliday, in which thiouracil agranulocytosis developed during penicillin treatment for otitis media, was interesting but very unusual. Surely the only, but important, lesson is: During thiouracil treatment, if the patient needs penicillin or a similar antibiotic, she also needs weekly leucocyte counts, since penicillin will suppress the usual warning symptoms.

Dr Holliday has made a useful tabulation of the published cases of thiouracil agranulocytosis, but the expected finding that agranulocytosis without symptoms has a better prognosis than that with symptoms gives no clue to the optimum method for supervision. How many blood counts had to be done to discover these 11 cases one to three days before the onset of their symptoms? None appear to have had their symptoms averted. It is unfortunate that his tables do not state the intervals between the onset of symptoms of agranulocytosis and both the cessation of thiouracil and the start of penicillin therapy. I do not know of any fatal cases where these intervals have been short. Only a serious risk of this outcome could justify including regular blood-counts in the routine of thiouracil treatment—excepting, of course, when an antibiotic is also being administered. A thyrotoxic patient is usually sufficiently nervous because of her disease.

RUSSELL FRASER

PROSPECT OF WAR

SIR,—The correspondence initiated by Professor Penrose and his colleagues indicates considerable strength of feeling on the questions they raise, but does not by any means show the same unanimity of opinion.

Dr Adair Girby (Jan 27) refers to the Society for Social Responsibility in Science, an American organisation whose activities would probably be admired by all, and he asks that a comparable lead be given in this country.

I should like to draw attention to the activities of the Cambridge Scientists' Anti-War Group, which, though small, attempts to express the views of scientists who have the interests of humanity at heart. Recently, for example, we organised a petition among Cambridge scientists condemning the development of the hydrogen bomb. We have held a conference on secrecy in science, and are just completing a book in which are contrasted the effects on science of war and war preparations, and the possibilities that can be envisaged in a world at peace. We have dealt with topics of immediate concern, including, on the one hand, biological warfare, and, on the other, the world requirements for food and the necessities for their fulfilment.

In view of the seriousness of the present situation, we are calling a national conference of scientists, medical and otherwise who share our aims. We hope that this will lead to the formation of similar groups in universities and laboratories elsewhere, and perhaps to the formation of a national scientists' organisation. At this conference we plan to discuss those aspects of the present political situation that affect both the scientist and his science. Prominence will be given to the special responsibility of scientists who are being called upon as never before to prostitute their work in the interests of a new and terrible war. All scientists are affected to some extent, but in many cases the connection is quite direct and explicit. The most glaring example, perhaps, is that of those physicians and their colleagues who are now

---

1 Livingstone R Street E W *Lancet* 1950 ii 308

being asked to make the weapons of biological and chemical warfare One session of the conference will be devoted to a discussion in more general terms of what can be done by scientists to prevent the present drive towards war

I hope you will allow me, through your columns, to ask medical scientists who would like to attend the conference to communicate directly with us We wish to bring together all those who feel that scientists must take a stand in defence of their science If we can find a basis for common action we will serve both our own good interests and those of all mankind

S M HILTON

Cambridge Scientists Anti War Group

8 Harvey Road
Cambridge

SIR,—Statesmen of all countries claim to be working for the welfare of man, each claims that his is the true path of social salvation, and with even greater vehemence that all other paths lead to deserts and waste places, not to the lands of milk and honey There are three chief systems to choose from, the competitive, the compulsive, and the cooperative, and each has its sincere advocates

Nullius in verba May we not, as men of science, suggest to the disputing statesmen that they put their systems to the test of experiment The world is big enough Let Russia, China, and such other countries as wish to follow them continue to govern by the strictest Marxian principles, let the New World follow even more zestfully the American Way of Life, and let Western Europe and the British Commonwealth struggle hopefully towards the more difficult goal of voluntary cooperation After a sufficient period, say three human generations, there would be no need to argue or to assert, the facts would be plain There are measurable indices of social health, such as the infant mortality rate, the net reproduction rate, the tuberculosis death rate, the suicide death rate, the V D incidence rate, and the mental disease rate The Statistical Section of the World Health Organisation could frame schedules for the experiment, and afterwards analyse the data Interim reports could be published, say every ten years, and the participating countries could see where they were strong and where they were falling behind It would be better and wiser to compete in a health race than in another arms race, and in such a cause every doctor could give his whole strength to his country's effort

This is the scientific way of solving disputes, an appeal to reason, not to prejudices and fears, to facts, not to force, to measurement, not to argument I feel we are justified in urging its value on all who will hear us

Cragdale, Settle D P LAMBERT

SIR,—*Your correspondents of Jan 20 might have* condemned war and arming for war, as human activities, even more roundly That all the "great nations" and many small ones are either fighting or arming, and that neither good will nor good sense, neither belief in goodness and justice nor enlightened self interest, stops them seems to me the final demonstration of human obliquity and folly Well may we confess, as units of humanity, that "there is no health in us" Should we catch our fellow citizens or our leaders preparing aggression I trust we should "in the spirit of our chosen profession of healing" protest

But we shall not so catch them To call this nation "peace loving" is an exaggeration, for love is a warmer, livelier emotion than we now, as a nation, seem able to feel for anything, good or bad But that we have a profound aversion from arming for or making war surely cannot be doubted by any unbiased observer seeing us from within or, I should have thought, from Moscow or Peking We went far in disarmament between wars, can any doubt that, with any practical encourageme from the East, we should go further now?

We all know that we are not preparing for aggressive war Are we justified in preparing for armed defence? Not if it is possible to reach a trustworthy "live and let live" agreement, sealed by disarmament, with the Communist powers, still less if, in our hearts, we are weary of freedom—the freedom to think, to believe or disbelieve, to choose the better or the worse But suppose we still cherish these freedoms and the real choice is between standing to arms and Communism here in our time, what then?

From Russia little news comes, but men who seem good witnesses talk to us soberly of what they have seen and heard in China and in Prague, and the story is always the same and matches the rumours from Russia and the sentiments, arguments, and slogans of our domestic Communists Thought and belief are not free, the end justifies the means, there are no absolute values in science, art, or life—no unqualified truth, beauty, or goodness "Whosoever will be saved must *thus think*" There is more besides, but this is enough Can members of our high profession stand for this?

But can arms defend us? Who can say? Doubtless real love of liberty, zeal for our free institutions, displayed not in words or votes but in work, is the best defence, but history suggests there is a place for arms At Marathon and Salamis the Greeks fought for their civilisation, of which free thought was the very heart They won, and if our medicine today is in debt to Greek thinkers, and our professional ethics to the Hippocratic standards of conduct, then they are in debt also to Greek arms and those who used them In 1588 we and the Netherlanders fought on the sea to defend our freedom to believe or to disbelieve, to decide for ourselves between right and wrong They won, and if medical research and practice here today need not swerve to avoid conflict with ecclesiastical dogma we owe it, in part, to those ships and sailors In 1914 we, and many other nations fought to keep out the philosophy of Nietzsche and Bernhardi, the doctrine that might is right We kept it out "They stood, and earth's foundations stay" But we went slack and in 1939 we had to fight again, this time against a direction of thought and enslavement of the mind, most definitely invading medicine, which seems to most of us twin brother to Communism The cost was hideous "Victory of desolation" is perhaps a fair phrase, but we do keep our freedom to believe, to think, to choose, to decide, to be kind and tolerant, not to hate or despise those of some class, nation, or economic status not our own

If only arms will defend these things must we not arm, whatever the cost?

London, N W 3 LINDSEY W BATTEN

SIR,—The possibility of doctors being able to outlaw war by concerted action is, unfortunately, a pipe dream Our opinions and ideologies cover too wide a range to allow of cooperation for any purpose—this is frequently shown, even within the bounds of this one little country

There is, however, no doubt that most people (and most doctors) detest war Most men will not work actively and voluntarily for a thing they do not want, but curiously enough, most people (and most doctors) will work for war Surely we should reorientate ourselves and work for peace?

Peace starts at home and in small communities If even some of those who hate war will work for friendship between men at home and abroad, and will do their best to lessen or eliminate injustice, prejudice, and misunderstanding, we may slowly move towards peace I believe there is no short cut

London E 11 J BARNARD

Public Health

Influenza

In England and Wales influenza continues to be generally prevalent In many areas, including the North and North-west, the incidence is declining, in other areas, more lately attacked, the peak may not yet have been reached. The disease is usually mild, and the causative virus is now clearly A-prime

In the week ended Jan 27 influenza deaths in the great towns totalled 1239—a rate of 59 7 per million population, compared with 54 per million in the previous week In each of the weeks from that ended Dec 9 to that ended Jan 20 the totals were 34, 33, 54, 102, 458, 890, and 1099 Figures for deaths during the week ended Jan 27 in the great towns grouped regionally show decreases in the Northern and North western regions, though the rate for the North-west (104 9 per million population) is still the highest There were decided increases in the North Midland, Midland, Eastern, and South-western regions and in Wales, and less significant increases in the East and West Ridings and the London and South eastern areas, in the Southern region there was a very slight drop More than 86% of the deaths were of patients over the age of 55

Influenza Abroad—The position abroad was reviewed last week (p 286) The disease is now reported to be prevalent in Yugoslavia, and the type of virus is stated to be B Influenza reported from Israel seems to be due to virus A-prime The disease is also prevalent in Japan, but the type of virus is not yet known

Estimate of Births

The Registrar-General's [1] final estimate of live births to be expected in England and Wales during the quarter ended March 31 is 178,000, and the provisional estimate for the quarter ended June 30 is 175,000 This would bring the total for the first six months of this year to 353,000, compared with 361,846 in the first half of 1950

Poliomyelitis

Since Jan. 1, 1950, doctors notifying poliomyelitis in this country have been required to distinguish between paralytic and non-paralytic forms In charting the weekly totals for 1950 (fig 1) we have therefore included the curve for non-paralytic cases The proportion of non-paralytic cases has been found to vary widely in different parts of the country, and, as the chart shows, the proportion tends to rise as the epidemic approaches its peak.

Relation to Weekly Temperature

In fig 2 the mean weekly temperatures at Kew have been charted with the poliomyelitis notifications for the county of London in the last few years It will be seen that in all three epidemic years the epidemic began in the week when the temperature first reached 60°F, and in 1949 and 1950 the epidemic began to recede when the temperature first fell below 60°F Dr Ian Taylor, of the Public Health Department, London County Council, who compiled this chart, remarks that, despite its obvious fallacies, the curve seems to show that poliomyelitis is associated in an "all or nothing" manner with the attainment of a critical atmospheric temperature

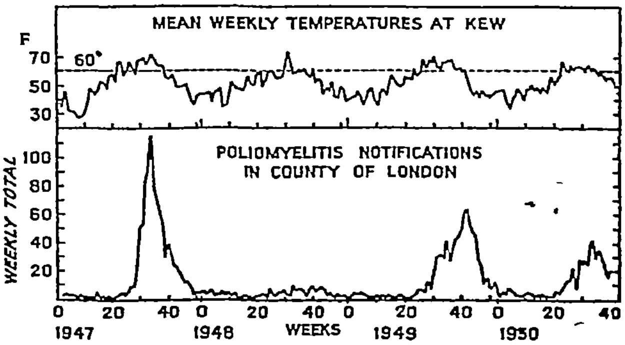

Fig 2—Poliomyelitis in County of London related to mean weekly temperatures at Kew

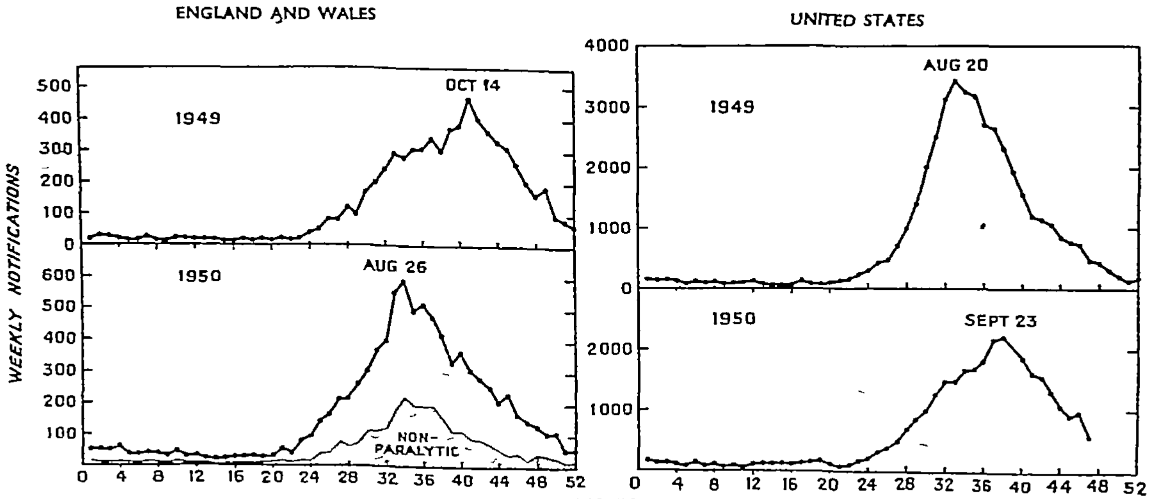

Fig 1.—Weekly notification of poliomyelitis in 1949 and 1950 showing dates of epidemic peaks. These were unusually late in England and Wales in 1949 and in the U.S A. in 1950 The chart for England and Wales in 1950 shows the proportion of non paralytic cases (stippled area)

Obituary

WILLIAM EWART BARNIE-ADSHEAD

M.B. Birm., B.Sc., F.R.C.S., F.R.C.S.E., F.R.C.O.G.

Dr W. E. Barnie-Adshead, gynæcologist and obstetrician to the Birmingham United Hospitals, who died on Jan. 26 at the General Hospital, Birmingham, was born at Dudley in 1901. He entered the Birmingham Medical School in 1917, and his friendliness and good nature soon made him popular with his fellow students, who elected him their representative on the Guild of Undergraduates and president of the Medical Students Union.

After taking his B.SC. in 1920 and his M.B. in 1923, he held resident posts at the Queen's Hospital, the General Hospital, and the Birmingham and Midland Hospital for Women. He also worked for a time in the London Hospital, before he obtained the fellowships of two Royal Colleges of Surgeons in 1926. In the same year, at an unusually early age, he was appointed assistant obstetrician and gynæcological surgeon to the Queen's Hospital at Birmingham. Here he was junior to Mr Lewis Graham, on whose teaching and example he largely founded his own practice. In 1929, he joined the staff of the Women's Hospital as surgeon.

One of the first members of the Royal College of Obstetricians and Gynæcologists he became a fellow in 1938, and he was lately elected to the council. For many years he was lecturer and examiner in obstetrics and gynæcology to the University of Birmingham, and his students appreciated the value of his straightforward and direct teaching. He was also lecturer and examiner to the Central Midwives Board.

As a student he was remarkably good at games. He captained the university soccer and cricket teams, and he was also a member of the tennis and golf sides. For a season he played cricket for Worcestershire, and he is remembered as a sound bat and a brilliant fieldsman. He was one of the best amateur footballers of his time, and for two seasons he was an English international halfback. Later, when he had less time for games, he still played every year in the Birmingham doctors *v.* clergy cricket match. But golf became his main interest. As well as playing himself, he generally managed to watch the Open Golf Championship and it was a great pleasure to him to encourage his two sons in their progress in the Boys' Open Championship.

"Those who knew Barnie-Adshead well," writes F. S. T., "recognised in him a man of the highest integrity, with deep convictions. Modest about his own merits, he did not try to create an impression but tended rather to minimise his achievements. His views were known to be unprejudiced and were listened to with respect. One of the kindest of men, he was very reluctant to criticise or impute unworthy motives to others. His charm of manner and natural sympathy and understanding made him popular with his patients, and his colleagues valued his sound clinical judgment. As an operator he was reliable and safe, deliberate but quick, and with no striving after effect. 'Barnie' had many friends both inside and outside the profession. It was a great grief to them to learn that he, who had always seemed so full of vitality, had been stricken. Those who visited him during his illness were impressed, though not surprised, by his courage and fortitude."

J. F. B. writes: "'Perhaps it was because of his perfect natural physical abilities that Barnie-Adshead was above all the misfortunes of ambition. The affection of his patients, his successes in his surgery came as naturally as his games—for he was a first-class sportsman in football, cricket, golf, and tennis. His counsel was at all times thoughtful and free from bias, and his happy outlook brought good fellowship where there might have been estrangement. His memory will always be cherished by those fortunate enough to be associated with him, particularly those of us who were his fellow students and shared his confidence. In the prime of his condition his astounding courage in facing the inevitable will always be an inspiration."

He leaves a widow, Dr Eileen Adshead, and two sons, both of whom hope to become doctors.

Notes and News

CODE OF SURGICAL OPERATIONS

The Registrar General announces that the first draft of a Code of Surgical Operations has been prepared with the help of his Advisory Committee on Medical Nomenclature and Statistics, and making full use of existing American classifications. The 3-figure code is divided into fifteen main sections according to the surgical specialty or broad anatomical location of the operation, with subsections giving greater detail of the site. Within each subsection is a grouping, according to the different operational procedures, with tabular lists of the principal ones included in each category. The draft code is being tried in certain hospitals and it is hoped that, with amendments resulting from this trial, a provisional code for wider use may be issued in 1952. The provisional code will form the basis of this country's recommendations to W.H.O. for an International Code of Operations to supplement the International Statistical Classification of Diseases, Injuries, and Causes of Death.

VOLUNTARY WORK FOR OUR HOSPITALS

The pattern of our social services is changing, and the National Council of Social Service are wisely reconsidering the proper place of the voluntary worker in the new régime. With the financial support of King Edward's Hospital Fund they are making a special study of voluntary services in the new hospital system. Mr John Trevelyan, former director of education for Westmorland, is the director of the inquiry, and the advisory committee consists of Lady Norman (chairman), Dr Janet Aitken, Mr S. F. Burman, Sir Wilson Jameson, F.R.C.P., Mr G. Mitchell, and Dr Keith Murray.

TUBERCULOUS IMMIGRANTS

The regulations for the medical examination of immigrants have lately been discussed by the Joint Tuberculosis Council. They fear that among the people who come to settle in this country there may be undetected cases of tuberculosis. At a recent meeting of the council Dr Sybil Horner, who is observer for the Ministry of Labour, described the procedure of that Ministry for dealing with the immigrants they sponsor, most of whom are Italians. These immigrants are examined in Italy, according to standards laid down by the Ministry of Health, by doctors appointed by the Italian ministry of labour. A miniature chest X ray is made followed by a full-sized film where necessary, but it is not known whether the doctor who reports on the film is always of consultant status. The miniature film is included in the immigrant's dossier and is available to the port medical officer, who himself examines the immigrants at the port of entry. The immigrants are first sent to a reception centre in London and then to a depot in Oldham till they are dispersed to their places of employment. Further medical examinations could be carried out at either of these centres if necessary. The Ministry of Labour, Dr Horner said, would be glad to know of instances of people reasonably suspected of having tuberculosis before immigration who had been accepted under the scheme. Some of the trouble in the past might, she thought, have been with displaced persons from other war areas who are now no longer being brought over, or with people brought over by private arrangement, for whom no special provisions exist. The repatriation of tuberculous immigrants is difficult because they can only be sent home if they are fit to travel and willing to go. After hearing the measures taken at present, the council remained uneasy. The regulations, they thought, are not sufficiently stringent. It is essential, they hold, that the doctors who scrutinise the X-ray films should be of consultant status. Large films, as well as the miniatures, they also suggest should accompany the immigrant.

BRITISH STANDARD FOR CHILDREN'S COTS

This standard (B.S. 1694/1950) covers children's metal cots suitable for use in hospitals and similar institutions. The standard height of the cots to the top of the corner castings is 2 ft., but alternative heights of 2 ft. 3 in. and 2 ft. 6 in. have also been provided. Similarly a standard length of 4 ft. 6 in. has been adopted, but an alternative length of 5 ft. has been standardised for use in special cases. The dimensions of the gaps between the tubes and bars forming the ends and the sides are to be not less than 3 in. or more than $3^{1}/_{2}$ in., in order to avoid the risk of a child being trapped or injured. The standard does not prevent the incorporation of additional atures, such as a removable head end or an adjustable ack rest Copies of this standard may be obtained from the ales department of the British Standards Institution, 4, Victoria Street, London, S W 1 price 2*s* 6*d* A separate tandard covering wooden cots for domestic use is being repared

University of London

Dr Ian Donald has been appointed to the university readership in obstetrics and gynæcology at St Thomas s Hospital Medical School

Dr Donald graduated B.A at Cape Town in 1930 before beginning his medical studies at St Thomas s Hospital in London He qualified in 1937 and he held a registrarship at the General Lying in Hospital before returning to St Thomas s as first assistant in the department of obstetrics and gynæcology During the war he served with the medical branch of the R.A F and he was mentioned in despatches and appointed M.B E for his services He took the M.D Lond and the M R C.O G in 1947 At present he holds the posts of clinical tutor in obstetrics and gynæcology at St Thomas s and of chief assistant at the Chelsea Hospital for Women His published work includes a paper on Uterine Rupture

University of Manchester

Dr W H Trethowan has been appointed lecturer in psychiatry

Royal College of Physicians of Ireland

On Feb 2 the following were admitted to the membership J C Dutta, William McAdam, Mary B O Donnell

Association of Surgeons of Great Britain and Ireland

The annual meeting of the association will be held in Manchester on Thursday, Friday, and Saturday, July 19, 20 and 21 The programme will include discussions on Head Injuries (opener, Sir Hugh Cairns), Infections of the Hand (Mr R M. Handfield-Jones and Mr W Gissane), Carcinoma of the Colon (Mr C Naunton Morgan), Acute Pancreatitis (Dr H. T Howat) After history of the Amputee in Peripheral Vascular Disease (Mr W A Mackey and Prof George Perkins)

Faculty of Ophthalmologists

The annual general meeting will be held on Wednesday, March 28, at 2 30 P M

British Association of Otolaryngologists

The following have been elected officers of the association for 1950–51 president Mr V E Negus vice president, Prof F C Ormerod secretary Mr F C W Capps, treasurer, Mr W A. Mill.

Conference on Tuberculosis

The Socialist Medical Association and the London Trades Council are holding a conference on tuberculosis on Saturday, Feb 10 at 2 P M., at St Pancras Town Hall, Euston Road, N W 1 Further particulars may be had from the secretary of the council 5 Guildford Place, W C 1

Medical School for non-Europeans in South Africa

A letter on the medical education of Africans, which appeared in our issue of Nov 25, mentioned the Union government s intention to open a non European medical school It is now officially stated that the new school has been "swamped with applications from native Indian, and Coloured students from all over the Union" The aim of the school is to turn out at least 20 qualified non European doctors each year A special building is being erected to house the medical school at Durban Natal at a cost of more than £200 000, and it is to be ready by 1953 At present a few non Europeans are trained at European medical schools in the Union. When the separate school has been completed, "apartheid" will be applied to the study of medicine, and non Europeans will not be accepted in other schools

Dental Fellowships for Doctors

The Nuffield Foundation is offering fellowships of £500 to £800 to graduates in medicine and science to receive training that will qualify them to undertake teaching and fundamental research on dental health and disease Further particulars will be found in our advertisement columns

Princess Tsahai Memorial Hospital

A further £2000–£3000 is needed to complete the equipment of this hospital in Addis Ababa Donations should be sent to the hon. treasurers, Lord Horder and Lord Amulree, c/o Messrs Gould & Prideaux, 88, Bishopsgate, London, E C 2

Shortage of Hospital Beds

A deputation from the British Medical Association's General Medical Services Committee visited the Ministry of Health on Jan 30, to discuss the increasing difficulty experienced by doctors in finding hospital accommodation for acute cases According to a statement which was issued afterwards, a number of suggestions were made to the Ministry These were being considered, and discussions, to be attended by medical officers of regional hospital boards, would continue

Health Services Conference

A conference to bring together representatives from all branches of the National Health Service will be held in London at Church House, Westminster, from March 14 to 16 to discuss Administrative Problems of the Health Services Mr Henry Lesser will be in the chair, and speakers will include Dr A Talbot Rogers, Dr T Rowland Hill, Dr A Torrie, Dr J A. Scott, and Dr W G Patterson Further particulars may be had from the secretary of the Institute of Public Administration, 76A, New Cavendish Street, W 1

French Government Exchange Scholarships

Under a reciprocal arrangement with the Centre National de la Recherche Scientifique, the Medical Research Council invite applications from young graduates in medicine or science who have already had some experience in a branch of medical science, excluding clinical medicine, for two scholarships tenable at research institutions in France during 1951–52 Candidates must be of British nationality and have at least a working knowledge of French The stipend will be within the range of 40,000–60,000 francs a month, and married men will receive a supplementary allowance Forms of application, to be returned by March 31, may be had from the secretary of the council, 38, Old Queen Street, London, S W 1

Meeting of W H O Executive Board

A meeting of this board opened at Geneva on Jan. 22 with Dr H S Gear in the chair (see *Lancet*, Feb 3, 1951, p 297) On Jan 24 the board decided, in view of the international situation, to postpone the first meeting of the Committee for the Western Pacific Region, which is served at present by an office in Hong Kong the meeting was to have been held in March With regard to Europe, the board approved the convening this year of a special consultative committee, to discuss future activities On Jan 26 the International Antivenereal Disease Commission of the Rhine was formally created This, the first intergovernmental commission established within the framework of W H.O, includes Belgium, France, the Netherlands, and Switzerland, the German federal government will be represented by observers The commission, which will have its administrative centre in Strasbourg and a technical and medicosocial secretariat in Rotterdam is to coördinate the venereal disease services of the five Rhine bordering countries for the benefit of Rhine River boatmen, and, where necessary, it will establish diagnostic and treatment centres in the main river ports

On Jan. 29 the board discussed the proposed W H O budget of $8 300 000 for 1952 Several members doubted whether additional financial burdens should be imposed on governments, but Dr Brock Chisholm, the director general, declared that 1952 would be a crucial year for W H.O —a year in which the Organisation should decide whether it was going to 'become a parasite or a leader He believed that millions of people throughout the world were prepared to spend large sums of money for health rather than for defence, and in any case the small amounts asked of each government for world health could not prejudice the execution of other programmes The board, unable to agree referred the question of this budget to the Committee on Administration and Finance

Obituary

WILLIAM EWART BARNIE-ADSHEAD

M B Birm, B Sc, F R C S, F R C S.E, F R C O G

Dr W E Barnie-Adshead, gynæcologist and obstetrician to the Birmingham United Hospitals, who died on Jan 26 at the General Hospital, Birmingham, was born at Dudley in 1901 He entered the Birmingham Medical School in 1917, and his friendliness and good nature soon made him popular with his fellow students, who elected him their representative on the Guild of Undergraduates and president of the Medical Students Union

After taking his B SC in 1920 and his M B in 1923, he held resident posts at the Queen's Hospital, the General Hospital, and the Birmingham and Midland Hospital for Women He also worked for a time in the London Hospital, before he obtained the fellowships of two Royal Colleges of Surgeons in 1926 In the same year, at an unusually early age, he was appointed assistant obstetrician and gynæcological surgeon to the Queen's Hospital at Birmingham Here he was junior to Mr Lewis Graham, on whose teaching and example he largely founded his own practice In 1929, he joined the staff of the Women's Hospital as surgeon

One of the first members of the Royal College of Obstetricians and Gynæcologists he became a fellow in 1938, and he was lately elected to the council For many years he was lecturer and examiner in obstetrics and gynæcology to the University of Birmingham, and his students appreciated the value of his straightforward and direct teaching He was also lecturer and examiner to the Central Midwives Board

As a student he was remarkably good at games He captained the university soccer and cricket teams, and he was also a member of the tennis and golf sides For a season he played cricket for Worcestershire, and he is remembered as a sound bat and a brilliant fieldsman He was one of the best amateur footballers of his time, and for two seasons he was an English international halfback. Later, when he had less time for games, he still played every year in the Birmingham doctors *v* clergy cricket match But golf became his main interest As well as playing himself, he generally managed to watch the Open Golf Championship and it was a great pleasure to him to encourage his two sons in their progress in the Boys' Open Championship

"Those who knew Barnie-Adshead well," writes F S T, "recognised in him a man of the highest integrity, with deep convictions Modest about his own merits, he did not try to create an impression but tended rather to minimise his achievements His views were known to be unprejudiced and were listened to with respect One of the kindest of men, he was very reluctant to criticise or impute unworthy motives to others His charm of manner and natural sympathy and understanding made him popular with his patients, and his colleagues valued his sound clinical judgment As an operator he was reliable and safe, deliberate but quick, and with no striving after effect 'Barnie' had many friends both inside and outside the profession It was a great grief to them to learn that he, who had always seemed so full of vitality, had been stricken Those who visited him during his illness were impressed, though not surprised, by his courage and fortitude"

J F B writes "Perhaps it was because of his perfect natural physical abilities that Barnie-Adshead was above all the misfortunes of ambition The affection of his patients, his successes in his surgery came as naturally as his games—for he was a first-class sportsman in football, cricket, golf, and tennis His counsel was at all times thoughtful and free from bias, and his happy outlook brought good fellowship where there might have been estrangement His memory will always be cherished by those fortunate enough to be associated with him, particularly those of us who were his fellow students and shared his confidence In the prime of his condition his astounding courage in facing the inevitable will always be an inspiration"

He leaves a widow, Dr Eileen Adshead, and two sons, both of whom hope to become doctors

Notes and News

CODE OF SURGICAL OPERATIONS

THE Registrar General announces that the first draft of a Code of Surgical Operations has been prepared with the help of his Advisory Committee on Medical Nomenclature and Statistics, and making full use of existing American classifications The 3 figure code is divided into fifteen main sections according to the surgical specialty or broad anatomical location of the operation, with subsections giving greater detail of the site Within each subsection is a grouping, according to the different operational procedures, with tabular lists of the principal ones included in each category The draft code is being tried in certain hospitals and it is hoped that, with amendments resulting from this trial, a provisional code for wider use may be issued in 1952 The provisional code will form the basis of this country's recommendations to W H O for an International Code of Operations to supplement the International Statistical Classification of Diseases, Injuries, and Causes of Death

VOLUNTARY WORK FOR OUR HOSPITALS

THE pattern of our social services is changing, and the National Council of Social Service are wisely reconsidering the proper place of the voluntary worker in the new régime With the financial support of King Edward's Hospital Fund they are making a special study of voluntary services in the new hospital system Mr John Trevelyan, former director of education for Westmorland, is the director of the inquiry, and the advisory committee consists of Lady Norman (chairman), Dr Janet Aitken Mr S F Burman, Sir Wilson Jameson F R C P, Mr G Mitchell, and Dr Keith Murray

TUBERCULOUS IMMIGRANTS

THE regulations for the medical examination of immigrants have lately been discussed by the Joint Tuberculosis Council They fear that among the people who come to settle in this country there may be undetected cases of tuberculosis At a recent meeting of the council Dr Sybil Horner, who is observer for the Ministry of Labour, described the procedure of that Ministry for dealing with the immigrants they sponsor, most of whom are Italians These immigrants are examined in Italy, according to standards laid down by the Ministry of Health, by doctors appointed by the Italian ministry of labour A miniature chest X ray is made followed by a full sized film where necessary, but it is not known whether the doctor who reports on the film is always of consultant status The miniature film is included in the immigrant's dossier and is available to the port medical officer, who himself examines the immigrants at the port of entry The immigrants are first sent to a reception centre in London and then to a depot in Oldham till they are dispersed to their places of employment Further medical examinations could be carried out at either of these centres if necessary The Ministry of Labour, Dr Horner said, would be glad to know of instances of people reasonably suspected of having tuberculosis before immigration who had been accepted under the scheme Some of the trouble in the past might, she thought, have been with displaced persons from other war areas who are now no longer being brought over, or with people brought over by private arrangement, for whom no special provisions exist The repatriation of tuberculous immigrants is difficult because they can only be sent home if they are fit to travel and willing to go After hearing the measures taken at present, the council remained uneasy The regulations, they thought, are not sufficiently stringent It is essential, they hold, that the doctors who scrutinise the X ray films should be of consultant status Large films, as well as the miniatures, they also suggest should accompany the immigrant

BRITISH STANDARD FOR CHILDREN'S COTS

THIS standard (B S 1694/1950) covers children's metal cots suitable for use in hospitals and similar institutions The standard height of the cots to the top of the corner castings is 2 ft, but alternative heights of 2 ft 3 in and 2 ft 6 in have also been provided Similarly a standard length of 4 ft 6 in has been adopted, but an alternative length of 5 ft has been standardised for use in special cases The dimensions of the gaps between the tubes and bars forming the ends and the sides are to be not less than 3 in or more than $3^1/_2$ in, in order to avoid the risk of a child being trapped or injured The standard does not prevent the incorporation of additional

MYOCARDIAL ISCHÆMIA AND ITS SURGICAL RELIEF*

GEORGE A MASON
V.R.D., F.R.C.S

SENIOR SURGEON, REGIONAL THORACIC SURGERY CENTRE, SHOTLEY BRIDGE HOSPITAL, NEWCASTLE UPON TYNE

THE term cardiac ischæmia, or preferably myocardial ischæmia, conveniently denotes anæmia of the heart muscle, generally due to degenerative and obstructive changes in the coronary vessels—coronary artery sclerosis.

Morgagni recognised coronary vessel sclerosis post mortem in 1707 and described it in his *De Sedibus et Causis Morborum* (1761):

> “As I examined the external surface of the heart, the left coronary artery appeared to have been changed into a bony canal to the extent of many fingers breadth, where it embraces the greater part of the basis. And part of that very long branch, also, which it sends down upon the anterior surface of the heart, was already become bony to so great a space, as could be covered by three fingers placed transversely.”

Attention may be drawn very forcibly to the presence of myocardial ischæmia by an attack, or attacks, of angina pectoris, a term usually associated with the name of Heberden, who named and described it in 1772. The description which follows is taken from his *Commentaries*, published in 1802, and is as good as any which has been given since:

> ‘But there is a disorder of the breast marked with strong and peculiar symptoms, considerable for the kind of danger belonging to it, and not extremely rare, which deserves to be mentioned more at length. The seat of it, and the sense of strangling and anxiety with which it is attended, may make it not improperly called angina pectoris.
>
> “They who are afflicted with it, are seized while they are walking (more especially if it be up hill, and soon after eating) with a painful and most disagreeable sensation in the breast, which seems as if it would extinguish life, if it were to increase or to continue; but the moment they stand still, all this uneasiness vanishes.
>
> “In all other respects the patients are, at the beginning of this disorder, perfectly well, and in particular have no shortness of breath, from which it is totally different. The pain is sometimes situated in the upper part, sometimes in the middle, sometimes at the bottom of the os sterni, and often more inclined to the left than to the right side. It likewise very frequently extends from the breast to the middle of the left arm. The pulse is, at least sometimes, not disturbed by this pain, as I have had opportunities of observing by feeling the pulse during the paroxysm. Males are most liable to this disease, especially such as have past their fiftieth year.
>
> “After it has continued a year or more, it will not cease so instantaneously upon standing still; and it will come on not only when the persons are walking, but when they are lying down, especially if they lie on the left side, and oblige them to rise up out of their beds. In some inveterate cases it has been brought on by the motion of a horse, or a carriage, and even by swallowing, coughing, going to stool, or speaking, or any disturbance of mind. The termination of angina pectoris is remarkable. For if no accident intervene, but the disease go on to its height, the patients all suddenly fall down and perish almost immediately. Of which indeed their frequent faintness, and sensations as if all the powers of life were failing, afford no obscure intimation.”

Jenner (cited by Gibson 1898) is said to have suggested that the symptoms of myocardial ischæmia might be due to coronary disease. Brunton (1867), considering that angina might be due to vascular spasm, relieved it with amyl nitrite inhalations.

The coronary vessels when sclerosed are particularly liable to thrombosis, and the resulting increased or even completed obstruction causes necrotic changes or inflammation in the heart muscle—coronary thrombosis. Herrick (1912) showed that the severity of coronary thrombosis varied in different patients, that it could often be diagnosed during life, and that a patient could and often did recover from an attack.

John Hunter is an early reminder that this is often a “doctor's disease,” and his suffering from it, the manner of his death, and the necropsy findings were fully described by his brother-in-law Edward Home (1794).

Angina is now generally regarded as due to myocardial anoxæmia; this is almost always a consequence of coronary sclerosis and, though occasionally it may be due to such causes as severe anæmia, paroxysmal tachycardia, or hyperthyroidism, there is often an associated vascular disease.

Levine (1936) and others have emphasised that “angina pectoris” and “coronary sclerosis” are not synonymous. The absence of the former does not exclude the presence of the latter. Though there are almost always associated structural changes in the coronary vessels if angina is present, it cannot be too strongly emphasised that they are often present without angina—just as the absence of claudication does not necessarily exclude peripheral sclerosis.

Clinically, though myocardial ischæmia is often manifested acutely and even dramatically by angina or coronary thrombosis, in many cases its indications are more insidious: there may be shortness of breath on exertion, a sense of oppression in the chest, or other sign of cardiac dysfunction, such as congestive failure, auricular fibrillation, or heart block.

Thrombotic obstruction of certain large vessels is constantly associated with characteristic areas of infarction. The descending branch of the left coronary artery is a favourite site for occlusion, and infarction of the anterior wall of the left ventricle and of the apex results.

The infrequency with which an area of infarction (or subsequent fibrosis) extends through the whole thickness of the wall, but rather extends some distance along it, has been emphasised by King (1941). If this were not so, ventricular aneurysm and rupture would occur more often. The main vessel may escape, and thromboses in the smaller branches tend to be multiple. Sometimes these are difficult to detect by the naked eye, and microscopical examination is required. The affected muscle degenerates and its place is taken by sclerotic tissue; hence irregular areas of fibrosis may be found throughout the heart.

By escaping thrombosis the narrowing of the larger vessels may proceed more slowly, and a diffuse replacement fibrosis of the heart muscle in the affected area results. Death eventually takes place, either slowly from progressive heart failure or suddenly from a fatal “heart attack.” Beck (1943a) has sought to reproduce the latter experimentally, and describes the mechanism graphically:

> “The fatal heart attack is similar to a convulsive seizure. It is now recognised that an area of anoxemia in the brain gives rise to a convulsion. This focus on the brain has been referred to as a trigger. The trigger discharges and from it emanate impulses to other parts of the brain. These produce a generalised convulsion. An analogous condition exists in the heart. A trigger can be made by ligation of four or five coronary channels supplying an area of heart muscle two or three centimetres in diameter. This area of myocardium becomes cyanotic after these arteries are ligated and suddenly something happens which destroys the coördinated heartbeat. Some fibres are contracted while others are elongated and the ventricles become a writhing squirming mass of muscle which does not pump out any blood. The term ventricular fibrillation is applied to this condition and, as you know, it is fatal. It is similar to a convulsion of skeletal muscle and the term

* A guest lecture given in the department of surgery, Postgraduate Medical School of London, on June 9, 1950.

Scholarships Abroad

The British Council has published a handbook describing some seventy scholarships, mostly for postgraduate study, which are offered by fifteen foreign governments and universities to British students for the academic year 1951–52 The headquarters of the British Council are at 65, Davies Street, London, W 1

CORRIGENDUM

Surgery in Sciatica and Low Back Pain

Owing to the omission of a sentence from their typescript, the final section of the article by Mr Burns and Mr Young last week (p 245) may convey an impression very different from the conservative views expressed in the rest of the article The missing sentence was the first, and the section should read

"*Summing up*

When operation has been decided on, the choice of operation is made as follows

If there are well marked physical signs indicating a protrusion *the disc should be exposed and removed* If the physical signs are slight, as in many cases of chronic lame back the lesion will be neither well defined nor what we have called 'ripe', in these patients grafting will usually be preferred In a few cases the decision will be difficult, then one may choose to inspect the disc and, if the findings are indefinite, do a fusion at the same operation"

coronary artery. Fauteux and Palmer (1941), recalling work in the 1914–18 war which demonstrated the increased safety attending ligation of a main artery when its corresponding vein was tied, experimented with ligation of the great cardiac vein. Ligation of this protected dogs from subsequent infarction after ligation of the coronary branch. This finding was applied to the treatment of coronary disease in 10 persons, of whom 9 had severe angina and the 10th had several attacks of coronary thrombosis; he was the only one to die soon after the operation, and death was said to be due to a tension pneumothorax. The 9 other patients were entirely freed from their anginal pain except 1, and he was much improved. 2 died, 1 three months later and the other thirty months later, and the remaining 7 were all well and working at their old jobs four to six years after operation.

It is suggested that mechanical distension of the direct arteriovenous communications, said to be present in the human heart, is the most important factor in Fauteux's operation. He later increased the scope of this to include removal of sympathetic and parasympathetic plexuses at the roots of the great vessels, thus interrupting impulses to and from the myocardium via the coronary vessels but not interfering with the pacemaker (Fauteux 1946). In 10 of these combined operations, 7 of the patients were free from pain and returned to work, but 2 were tired and complained of tightness in the chest. There were 3 postoperative deaths—2 from thrombophlebitis and 1 from coronary occlusion three months later. It is not known to what extent pericardial adhesions (which might in themselves be beneficial) have formed in these cases.

Beck (cited by Blalock 1949) has done a great deal of new experimental work in which he has attempted, by anastomosing a systemic artery to the coronary sinus, to reverse the coronary circulation. He has found it possible to apply this procedure to patients with coronary insufficiency and success has been claimed. As severe and hazardous operations are entailed, and as the possibility of such a circulatory reversal has not yet been generally accepted, further knowledge of this work is required before its utility can be assessed.

Operations to Improve Vascularity of Heart Muscle by Initiating Surface Inflammation and Provision of Extracardiac Collateral Vessels

This is where my own interest has particularly lain. Neurectomy and thyroidectomy both imply acceptance of a vascular status quo in the myocardium; the proposition of bringing an additional blood supply thereto, or of insuring against further vascular catastrophes therein, seems much more attractive.

A close friendship with Laurence O'Shaughnessy enabled me to follow this work from the beginning. Like Beck he was one of the pioneers in both the experimental work (O'Shaughnessy 1936) and its clinical application. It has been proved, I think beyond question, that a collateral extracardiac circulation can be established, whether intercostal muscle, substernal fat, omentum, or lung be grafted or an artificial pericarditis alone be provoked. O'Shaughnessy's greyhound (O'Shaughnessy 1936), a host of injection pictures in the literature, and the protocols of experiments demonstrating the immunity with which coronary vessels can be tied after grafting, demonstrate the value of this method in the laboratory animal.

Beck's beautifully detailed experiments show that the provision of what he describes as a "blood bath" can prevent a myocardial trigger from discharging. This blood bath can be provided by improving the intercoronary anastomosis in the myocardium both by provoking inflammation on the surface of the heart and by grafting on to that surface some vascular tissue such as mediastinal fat, parietal pericardium, parietal muscle tissue, lung, or omentum. The experimental work referred to has shown that with a good successful graft innumerable small vessels, often minute, establish vascular continuity between the vessels of the graft and the coronary circulatory system rather than by the formation of large new vessels. However, it has been shown that the formation of these vessels seems to be, to some extent, in proportion to the degree of obstruction present in the original coronary vessels. It is, for instance, easier, in the experimental animal, to demonstrate formation of vessels after grafting, if the coronary artery to the grafted area has already been tied. Beck's work also seems to show that the new vessels, as well as the pre-existing anastomoses between the adjacent coronary arteries, can increase in size with slowly progressive occlusion of the coronary artery (Beck 1943b).

All O'Shaughnessy's results—and he had accumulated a considerable volume of material—are not available. After he was killed at Dunkirk, the key to his material was held by H. E. Mansell, the enthusiastic physician who coöperated with him. Mansell unfortunately died early in the war, and the records now seem to have been scattered. His latest figures in my possession are those published by Davies et al. (1938). Of 20 cases reported, 15 had angina, and 5 had other symptoms of cardiac ischæmia. Of the first group 5 died within three months of operation—1 of these from rupture of the ventricle during operation. Of the 10 who lived 8 resumed more or less normal life. In the second non-anginal group of 5 cases, 1 death was recorded; all 5 were much improved. The operations employed were cardio-omentopexy both transpleural and extrapleural, pericardiotomy with introduction of 'Aleuronat' paste, and cardiopneumopexy (Lezius 1937).

Strieder (1941) reported a case of a man, crippled by angina, who obtained very great, but not complete, relief from cardio-omentopexy but died suddenly six months later after the operative correction of partial herniation of the stomach through the diaphragm:

> "At autopsy, the graft was securely in place and on injecting the specimen through the superior mesentery artery, it was evident on section and on X ray that there was a rather rich vascular ingrowth from the raft into the myocardium. There was diffuse fibrosis throughout the myocardium."

The latest results I have of Dr. Beck's are those published by Feil (1943). Among 37 cases treated by Beck's technique there were 14 postoperative deaths. 9 patients who survived the operation but died from four months to six years later were studied after death: 4 showed little improvement, and in 5 the results had been excellent. Of the 14 patients who survived at the time of publication 9 were definitely improved, 5 showing an increase in exercise tolerance and diminution of symptoms.

Feil classified the results of the 23 who survived the operation as excellent 14, good 5, and little or no improvement 4. He says the operation gave relief to the 14 surviving when he wrote, and that 5 others had been greatly benefited. One of Beck's patients underwent successfully a course of convulsion therapy for depression—a pretty good rest.

Thompson and Raisbeck (1942) described as especially suitable for "poor risk" cases the insufflation of sterilised talc into the pericardial sac whereby an adhesive pericarditis might produce similar benefit. Thompson (1949) has reported a series of 36 seriously handicapped patients. Of these, 6 died and 26 of the remainder were improved, being classified as good or excellent; in 4 the results were poor, but 8 were completely relieved of their angina and considered themselves practically normal. The criteria of rehabilitation were relief of anginal pain, convulsion of the heart might well be applied to this condition I believe if we could actually observe the heart in fatal attacks we would prefer to use the term convulsion of the heart rather than ventricular fibrillation

"I should like to return to the experiment in which we ligated arterial channels to produce a trigger I should like you to visualise an experiment in which we ligate four small channels to a small area of myocardium We can observe the cyanosis of this small area of myocardium Now if we go no farther with our ligation we can close the operative wound and the animal will recover If we go ahead and ligate the fifth channel to this small area of myocardium the trigger will discharge, destroy *the coördinated beat, and produce death* This fifth small channel then can be regarded as the 'last straw' It makes the difference between life and death This vessel carries a small amount of blood, and a small amount of blood can make the difference between life and death This small amount of blood can be looked upon as a blood bath I do not think we can overemphasise the importance of a small amount of oxygenated blood delivered to that part of the heart where the blood supply is deficient Those who are adversely critical of this research will please bear in mind that a small amount of oxygenated blood can be significant It can save the life of the individual who has a trigger *zone developing in the heart I need scarcely remind you that* when death occurs from a heart attack it is usually sudden and unexpected Usually there are no signs of heart failure This is a physiological derangement and it is as effective as turning the ignition switch in a smoothly working motor The trigger zone may be important anatomically No doubt it could be excised experimentally if one cared to do so and the animal would be left with a good heart A new set of coronary arteries is not necessary to prevent a small localised trigger from discharging A blood bath can be effective"

Beck found repeatedly that the ligation of four or five small arteries over the left ventricle was a fatal procedure, the ventricle going into fibrillation Then he narrowed the two main coronary arteries, reducing their bore by about a third, and this degree of obstruction was tolerated In the second series of experiments a generalised anoxæmia was produced, compared with a localised but severe anoxæmia of a small part of the myocardium in the first series the former was tolerated, although the entire coronary circulation was reduced to a greater extent, and the latter was not

Injection experiments demonstrate the existence of anastomoses between the right and left coronary vessels, and these must provide some protection against the consequence of coronary occlusion These probably increase in number as well as in capacity when an inflammatory focus, such as that after an infarction, develops in the myocardium Pericardial adhesions are another source of vascular protection against the consequences of coronary occlusion , but King remarked on the astonishing infrequency with which they are found in view of the frequency of pericardial friction

Even so, clinically, I believe that the development of pericarditis in a case of coronary thrombosis is often welcomed as of good prognostic import Thus it may be that surface inflammation in disease has some beneficial effect on "deep" vascularity, as it does in experimental work

Feil (1943) has compiled a table from the literature showing the average duration of life *after* onset of the symptoms in several series of cases of coronary sclerosis The grave prognosis is obvious—in some 1728 cases the duration of life was 3 7 years His analysis of 256 cases in which death took place in Lakeside Hospital, Cleveland, from myocardial infarction and which had received conventional medical treatment, shows how short was the course run by the disease in most of the cases He says that medical therapy "does not in any way alter the underlying progress of these changes"

Palmer's (1937) statement, however, that 73% of patients may expect to be still alive at the end of four years, and 38% at the end of ten years, must be borne in mind We all know of people who have lived for many years after coronary thrombosis, but Palmer's figures presumably refer to survivors (after initial recovery), and my impression has always been that the prognosis is much worse than this—more approaching Feil's figures

SURGICAL TREATMENT

Probably almost as many people die of coronary disease as die of cancer and, as medical treatment is of little avail, it is important to see whether surgery has anything to offer At least it can offer an opportunity for the further study of "living pathology," and the taking of such opportunities elsewhere in the body has usually led to progress As Beck (1943a) says

> "If a car does not run, someone has to lift up the hood and look We are now entering the era of direct examination and manipulation in the cardiovascular field"

Surgical treatment to date can be considered under the following headings

(1) Attempts to reduce metabolic activity and thus the demands made on the heart

(2) Interruption of nervous pathways to eliminate pain.

(3) Stimulation of intercoronary compensating circulation by obstructing the flow in the cardiac veins

(4) Operations to improve the vascularity of the heart muscle by the provision of extracardiac collateral vessels

Attempts to Reduce Metabolic Activity

Attempts to reduce the strain on the heart by reducing the level of thyroid activity were made in the years between the wars (Blumgart et al 1933) Such treatment is really only palliative and condemns the patient to a reduced level of existence I have no experience of it and believe that it is now discarded Actually one of my better grafting results has been in a lady who could not, because of angina, take the thyroid extract necessary to control her (idiopathic) myxœdema

Interruption of Nervous Pathways

Jonesco's (1920) cervical sympathectomy, Leriche's stellate ganglionectomy (Leriche and Fontaine 1927) Mandl's (1925) injection and White's (1929) excision of the upper dorsal chain, Singer's posterior and Raney's (1939) anterior rhizotomy, and now Fauteux's pericoronary neurectomy are proceedings which have all had their advocates , indeed some are still practised Again, however, *they are only palliative* and cannot properly compensate the heart for its diminished blood supply—the essence of the condition—at any rate if anything like normal function is required of it.

Injections of the sympathetic ganglia may be indicated on humanitarian grounds and often relieve the distressing pain of a patient who is unsuitable for other procedures and resigned to a quiet life Great skill and accuracy is needed to "site" these injections and probably anæsthetists used to paravertebral and sympathetic injections are most suited to do this work The method is not *altogether free from risk, and* I have seen, especially where bilateral injection has been necessary, the consequent fall in blood pressure apparently initiate coronary thrombosis After injection neuritic intercostal pain may persist and may be extremely severe Palmer (1937) cites a patient who said that when he had his angina he was afraid he might die from it, but when he had neuritis he was afraid he might *not* die

Obstruction of Venous Return from Heart Muscle

Gross et al (1937) have shown that occlusion of the coronary sinus in the dog causes an increase in the coronary tree and in the intercoronary *anastomotic* vessels Preliminary preparations of a dog's heart in this way made it well nigh impossible to produce infarction by tying the anterior descending branch of the left

TABLE II—CASES UNRELIEVED

Case no	Age (yr)	Sex	Duration of symptoms	Disability	Blood pressure (mm Hg)	Operation	Post operative survival	Comment
13	53	F	9 months	Severe progressive angina on slightest exertion or excitement latterly bedfast	180/100	March 5 1937 general anæsthesia transpleural cardio omentopexy , graft stitched to heart	2 months	No relief necropsy showed graft diffusely adherent pericardial sac obliterated and chronic interstitial nephritis
12	58	M	18 months	Gross hypertension angina of effort (50 yards)	240/135	April 1 1941 general anæsthesia , pericardium opened through Larrey s angle , omentum applied to heart after application of aleuronat paste	2½ years	Slight relief only and eventually pain as bad as ever necropsy showed gross coronary atheroma large fatty heart with dilated right side, pulmonary congestion, and graft only adherent over small area
13	58	M	18 months	Angina of effort and breathlessness very neurotic and hypertensive	230/110	April 17 1949 general anæsthesia anterior cardio omentopexy omentum applied to heart abraded by asbestos powder	14 months	No relief admitted widespread pains breathless , gross hyperplesia very anxious difficult to assess no beneficial effect

liable to cause arrhythmias , hence for a while we preferred ether oxygen anæsthesia Latterly we have used light general anæsthesia with thiopentone, nitrous oxide, and oxygen, with curare to control excessive respiratory movements Cardiac irregularities due to manipulation of the heart are minimised by instilling 1% procaine into the pericardium and a continuous intravenous infusion of procaine in 0 2% or 0 1% solution

SURGICAL METHODS

The operative techniques used have varied with the condition of the patient and with increased experience Where the patient's general condition has been bad, an extrapleural pericardiotomy (Davies et al 1938) through Larrey's angle after removal of the 7th costal cartilage has been used, and either aleuronat paste smeared over the pericardial sac or asbestos powder insufflated into it In the earlier cases the original O'Shaughnessy anterolateral thoracotomy and transpleural exposure of the heart were used, and a pedicled graft of great omentum was brought up and applied to the heart In one of these cases a loop of colon passed up the centre of the omentum and became strangulated , now we pass "obstructing" stitches across the omentum between the margins of the diaphragmatic defect to obviate this

Later Beck's (1943b) revised approach was used With this the 3rd, 4th, and 5th left costal cartilages are removed, the pericardium being opened extrapleurally and between the intercostal bundles, which should be preserved The parietal pericardium was abraded with Beck's raspatories and then either smeared with aleuronat paste or asbestos powder insufflated into the sac However, if the condition of the patient permitted, the omentum was first brought up either through the linea alba or through the front of the medial part of the diaphragm—i e , either in front of or behind the costal margin, as convenient—and next piloted into the sac deep to the intercostal bundles, spread over the heart surface, and tacked to the pericardium For a long time we avoided suturing directly to the heart in these cases, but it is now felt that this probably need not be feared

If the pleura has been opened, either deliberately or accidentally, during the operation the lung should be fully inflated before the wound is closed

POSTOPERATIVE MANAGEMENT

Anoxæmia must be avoided Adequate oxygenation during the postoperative period is essential , for this purpose the B.L B mask is convenient, but the patient must be well watched lest any obstruction of the airway with consequent anoxæmia occurs In this connection the importance of radiographic control may be emphasised , an X ray photograph of the chest should be obtained as soon as possible after the operation , by this a pneumothorax or even an atelectasis may be detected and, if present, dealt with promptly Such examinations should be repeated frequently during the recovery period, because respiratory complications are particularly embarrassing in such cases

It is our custom to block the appropriate intercostal nerves in all our thoracotomy cases to minimise post operative pain and so encourage the early use of breathing exercises Even so it has been our experience that these patients suffer an unusual amount of pain after operation, possibly associated with pericarditis Hence adequate sedation must be provided , for this purpose morphine is used freely, and intravenous procaine seems to be helpful

Vascular thrombosis, coronary or cerebral, has been the cause of death in a significant proportion of cases in this series (table I) Rehn and Halse (1949) and others have shown that anticoagulation therapy has had apparently a definite prophylactic effect in preventing embolism and thromboses after surgical operations generally Accordingly at present we give heparin after the first twelve or eighteen hours for two days and thereafter rely on dicoumarol for two or three weeks Even though our incidence of complicating thromboses has fallen, as a result presumably of somewhat better selection of cases and the definitely improved handling of these in the light of experience, it seems worth while using these anticoagulants

Breathing exercises and active muscular movements, within the limits of the preoperative exercise in tolerance, are practised from the day after operation until the patient is allowed up, usually after an interval of at least a month Resumption of activity must only be gradual , otherwise patients attributing their freedom from pain to some miraculous effect of the graft may undertake too much, sometimes with serious consequences Such early freedom from pain is unlikely to be due to the graft but only to the rest in bed and perhaps to an improved intercoronary circulation such as occurs in the laboratory animal as a consequence of pericardial reaction

REVIEW OF CASES

The present series consists of 30 cases operated on during the past fourteen years The great majority of these were dealt with in the Newcastle upon Tyne Regional Thoracic Surgery Centre, formerly at the Newcastle General Hospital and now at Shotley Bridge Of these patients 11 died within a few weeks of operation , but 1 of the deaths was in a private case, operated on elsewhere in unsatisfactory circumstances, and it has increase of exercise tolerance, and ability of the patients to fend for themselves and return to gainful occupation †

SELECTION OF CASES

Most physicians still being sceptical about the utility of these operations, we have not been able to pick and choose our patients Most of those with whom we have been concerned have been bad risks and often, rendered desperate by their disability, have pleaded for operation Strangely enough, some of the worst cases have been most successful, whereas some of the "early" deaths occurred among the comparatively fit At necropsy, however, even these latter were always found to have had a more severe degree of coronary disease than had been appreciated clinically

Feil (1943) remarked that the operation mortality was highest among the first patients operated on, because these, who had angina on slight exertion, had serious coronary disease and associated cardiovascular changes In our series, although the type of case latterly has not much improved, the mortality has, however, we feel that the improvement has been due rather to improved technical handling Gross hypertension has not necessarily been regarded as a contra indication, and this possibly may have been an unfavourable factor in some of our cases, but, on the other hand, some of our favourable results have been in this group We have learnt to avoid cases showing gross cardiac enlargement, renal changes, or pulmonary infection Similarly, it seems better at present to reject those who have had multiple coronary infarctions and those in whom there is clinical, radiological, kymographic, and possibly electrocardiographic evidence of severe myocardial damage

Ideally, and in principle, grafting seems to be indicated for the relief of anginal pain and, in those who have had an infarction, as an insurance against the consequences of further thromboses

ANÆSTHESIA

I am indebted to Dr Joan Millar, our senior anæsthetist, for the following details of our current anæsthetic practice The choice of suitable anæsthetic agents for patients who have had coronary thrombosis is often difficult Many of these patients belong to the older age group and are apprehensive about the condition of their heart and its ability to withstand the strain of a major operation On the other hand, some of the worst operative risks are desperately anxious to avail themselves of any chance of relief and a return to something approaching normal existence Hypertension is often a complicating factor Immediate postoperative deaths in these patients are usually the result of a further coronary thrombosis or of cerebral thrombosis, hence a marked fall in blood pressure should be avoided On the one hand the circulation must not be overloaded with large quantities of intravenous fluids, on the other there must be no dehydration during the period when the patient cannot drink freely

We have found local anæsthesia unsuitable, the injection of local anæsthetic solutions and consequent delay in starting the operation have a demoralising effect, often making these patients grey, anxious, and liable to "anginal attacks" General anæsthesia is preferable, especially when the proposed operation involves opening the pleura or diaphragm Premedication should be light but adequate for a smooth induction with a cautious dose of thiopentone The subsequent anæsthetic technique must provide high concentrations of oxygen and light anæsthesia without excessive respiratory movements. Cyclopropane seems to have many advantages but is

TABLE I—EARLY POSTOPERATIVE DEATHS

Case no	Age (yr)	Sex	Duration of symptoms	Disability	Blood pressure (mm Hg)	Operation	Date of operation	Date of death	Cause of death
1	34	M	3–4 years	Unable to work angina of effort (100 yards) due to emotion and sometimes at rest	140/90	General anæsthesia transpleural cardio omentopexy graft sutured	July 19 1937	July 20, 1937	Pulmonary œdema and atelectasis
2	45	F	4 years	Angina with any effort (even at rest in bed) and emotion	245/160	General anæsthesia, transpleural cardio omentopexy graft sutured	Oct 18, 1937	Nov 26, 1937	Cerebral thrombosis

---

† Since this lecture was delivered Forrester Wood (1950) has reported 4 cases of angina apparently benefited in this way

his death Although there was no recurrence of his anginal pain after operation, the incapacity imposed by the trigeminal neuralgia made it impossible to test his exercise capacity

Two patients who had considerable relief from anginal pain and some increase in their exercise tolerance died five months after operation.

Case 16 —This man, who was thought to have syphilitic aortitis with aortic incompetence, died in another part of the country No necropsy was done, but his doctor informed us that he seemed to be doing well and was improving gradually until four days before his death, when he developed a severe precordial pain—unlike his previous angina—which was unrelieved by nitrites and was thought at the time to be due to his aortitis

Case 20 —This man was a severe case of myocardial ischæmia who possibly abused his newly found freedom from pain and attempted too much activity His dyspnœa, but not his pain, recurred, congestive heart failure developed, and he died At necropsy gross coronary atheroma and myocardial fibrosis were found The lung, which had been encouraged to adhere to the heart after removal of part of the pericardium on the left side and smearing with aleuronat paste, was diffusely adherent, and the pericardial sac obliterated The histological records cannot now be traced

Case 27 —This similar case is that of a female private patient who enjoyed her freedom from pain following operation so much that when discharged from hospital she at once resumed full activity, despite the protestations of her medical advisers Presumably as a consequence she developed, just two months after operation, a severe precordial pain, which was diagnosed as coronary thrombosis, and died within a few hours

Case 22 —A priest, aged 57, with gross hyperpiesia (230/130) who had had severe angina for three years, became much more comfortable after grafting and resumed some of his parochial duties Two years later, however, he began to have frequent severe attacks, each one resembling a major coronary thrombosis Only slight relief from the pain of these attacks followed a left-sided sympathectomy (Raney), and he died, four years after the original operation, from cerebral thrombosis No necropsy was done, but it seems possible (to put it at its lowest) that, apart from giving some relief for two years, the presence of the graft may well explain his long survival despite the many attacks regarded as major coronary thromboses

Case 21 —This lady, now aged 75, who was grafted in 1938, is another case from which a little encouragement may be derived Although pain was never completely absent it was considerably reduced during the early postoperative years The patient, however has gross hyperpiesis (340/240) and as long ago as 1947 had albuminuric retinitis Her doctor and her family are emphatic that she has undoubtedly benefited from the operation

Cases Deriving Benefit

Although 4 of the patients in this group are now dead, the circumstances of their deaths or the dispersal of pathological material and other records unfortunately make it necessary to rely on their clinical histories for final assessment

Case 14 —A joiner and general labourer, aged 63, had had angina for nine years and latterly been unable to work. After transpleural cardio omentopexy he was freed from disability and resumed work He remained free from any symptoms

TABLE III—*continued*

Case no	Age (yr)	Sex	Duration of symptoms	Disability	Blood pressure (mm Hg)	Operation	Post-operative survival	Comment
22	57	M	3 years	Severe angina precipitated by exertion heavy meals and emotion, unable to work as parish priest	230/130	June 23 1939 general anæsthesia transthoracic cardio-omentopexy graft sutured to heart	3¾ years	Considerable relief of symptoms and resumed duty for 2 years then repeated attacks resembling severe coronary thromboses died from cerebral thrombosis no necropsy
23	59	M	20 months	Coronary thrombosis in 1943 followed by anginal attacks on slight exertion almost confined to bed	210/130	Oct. 17, 1945 local followed by general anæsthesia abrasion of pericardium and insufflation of powdered asbestos (Beck)	4½ years +	Complete freedom from pain operated on for recurrent inguinal hernia in 1947, works as coalminer digging, and lifting girders &c
24	56	M	18 months	Coronary thrombosis followed by angina and dyspnœa on slight exertion	190/120	Dec 5 1946 general anæsthesia abrasion of pericardium and insufflation of powdered asbestos (Beck)	3½ years +	Free from pain and resumed work for 4 months pain and dyspnœa recurred with increasing obesity, now comparatively well after reducing weight
25	52	M	8 months	Coronary thrombosis followed by angina on exertion (2 or 3 steps) unable to work	210/130	Jan 2 1947 general anæsthesia anterior cardio omentopexy abrasion and insufflation of asbestos powder	3½ years +	Complete freedom from pain, can walk 7 miles runs to catch bus resumed work as colliery checkweighman
26	61	F	20 months	Angina of effort (10 yards), unable to take thyroid (required for myxœdema) without causing angina	150/100	Dec 5 1946 general anæsthesia transthoracic cardio-omentopexy graft fixed to heart by suture and asbestos powdering	3½ years +	Completely freed from pain can take necessary thyroid extract and lead ordinary life
27	53	F	2 years	Angina of effort (20 yards)	120/80	June 13 1947 general anæsthesia intercostal bundle sutured to heart, pericardium abraded and insufflated with asbestos (Beck)	2 months	Complete freedom from pain resumed too much activity too quickly and died with coronary thrombosis (presumed) 2 months after operation no necropsy
28	49	M	3½ years	Dizziness and angina of effort (100 yards) shortness of breath almost confined to bed unable to work	102/72	Nov 24 1949 general anæsthesia anterior cardio-omentopexy omentum applied to heart abraded by asbestos powder	7 months +	Complete freedom from pain can walk 2 miles, going to Australia for holiday
29	41	M	8 months	Anginal pain brought on by exertion (¼ mile) cold weather or heavy meals no relief by nitrites no improvement after a month s rest in bed	130/80	Jan 5 1950 general anæsthesia anterior cardio omentopexy omentum applied to heart abraded by asbestos powder	6 months +	Still has some pain on hurrying thinks he is better than before operation no dyspnœa improving on June 27 1950 reported complete recovery anxious to resume work exercise tolerance much improved

proved impossible to ascertain the cause of death or obtain any clinical details Except in so far as it weights the mortality figures, this case must be discarded from further consideration here

Details of the remaining 10 early postoperative deaths are set out in table I 7 patients died within the first three or four days, and, apart from 1 who died from œdema of the right lung and atelectasis of the left, and 1 patient with syphilitic aortitis, the deaths were due either to coronary or cerebral thrombosis Cerebral thrombosis was also the cause of death in 2 other patients dying three or four weeks later Another died from massive pulmonary embolism, originating from the calf, after a similar period It seems likely that subsequent improvements in anæsthesia and operative technique as well as in general management, would have enabled some of them to recover

3 patients (cases 11–13 in table II) definitely obtained no relief Fourteen months after operation 1 of these is still alive Another died two months and the third two years after operation, and in these the grafts had only the most slender attachment to the heart

Significant benefit to the myocardium from grafting is thought to have been derived by 16 patients (cases 14–29 in table III, where they are arranged in chronological order of date of operation)

Of these 16 patients there are 6 of whom at best it can only be said that there is possibly evidence of the graft having played a beneficial role, on the other hand, the 10 other cases show why I feel strongly that these grafting procedures can be of benefit to myocardial ischæmia It is necessary to consider both these groups in some detail

Cases Deriving Problematical Benefit

Case 18 —This man developed a virulent frontal herpes on the day after operation, and this was succeeded by severe trigeminal neuralgia, which persisted and completely incapacitated the patient until his death sixteen months later from congestive heart failure His heart fibrillated after the induction of the anæsthetic and again intermittently until

TABLE III—CASES PROBABLY DERIVING BENEFIT

Case no	Age (yr)	Sex	Duration of symptoms	Disability	Blood pressure (mm Hg)	Operation	Post-operative survival	Comment
14	63	M	9 years	Presternal pain inability to work as joiner and general labourer breathlessness on exertion (80 yards) or emotion	120/70	Nov 4, 1936 general anæsthesia transthoracic cardio-omentopexy, graft sutured to heart	9 years	Complete freedom from pain for 5 years and resumed work, some pain during past 4 years died of pancreatic carcinoma with metastases necropsy showed coronaries almost occluded graft generally adherent and communicating vessels involved in growth
15	47	F	7 years	Anginal attacks precipitated by emotion and exertion and occasionally at rest breathless on slight exertion	130/80	March 25 1937 general anæsthesia transthoracic cardio-omentopexy graft sutured to heart	4½ years	Normal life with freedom from pain for 4 years some recurrence of pain for last 6 months, died from pneumonia following sloughing pharyngitis necropsy showed gross coronary sclerosis and graft diffusely adherent
16	54	M	8 years	Severe anginal pain brought on by cold, straining at stool &c specific aortitis with incompetence suspected but Wassermann reaction negative	160/30	March 25 1937 general anæsthesia transthoracic cardio omentopexy graft sutured to heart	5 months	Relief from pain and improved exercise tolerance 5 months died after 4 days illness suggesting specific aortitis, no necropsy
17	51	M	2 years	Inability to work as brass founder because of severe anginal pain brought on by exertion (stairs) and emotion and occasionally at rest virtually confined to house	160/90	May 7, 1937 general anæsthesia graft fixed to heart	7 months	Complete freedom from pain and resumed work 7 months, died of paralytic ileus and bronchopneumonia 4 days after operative relief of colon strangulated through graft (unrecognised 48 hr)
18	59	M	2 years	Anginal pain brought on by emotion and exertion (700–800 yards)	158/90	June 4 1937 general anæsthesia graft fixed to heart	16 months	Free from angina but intermittent fibrillation died from congestive failure after 16 months impossible to assess exercise capacity because of trigeminal neuralgia following malignant frontal herpes no necropsy
19	62	M	12 years	Unable to work because of angina and shortness of breath on exertion Wassermann reaction positive	135/80	Feb 1 1938 general anæsthesia, precordial pad of fat laid against aleuronated surface of heart and pericardium transpleurally	4 years	Freedom from pain and dyspnœa with resumption of work for 2 years then retired with some recurrence of dyspnœa died in sleep, no necropsy
20	57	M	5 years	5 years' breathlessness on exertion angina on walking (200 yards) and occasionally on waking in morning claudication	170/90	Feb 18 1938 general anæsthesia pericardium and heart smeared with aleuronat lung sutured to pericardium and left to adhere to heart	5 months	Free from pain but dyspnœa on exertion resumed activity too soon and died of congestive failure necropsy showed gross coronary sclerosis and lung, heart, and pericardium diffusely adherent
21	63	F	1 year	Continuous anginal pain brought on by emotion and exertion (¼ mile) several syncopal attacks		May 1938 general anæsthesia transthoracic cardio omentopexy	12 years +	Considerable reduction in pain during early postoperative years now gross hypertension 340/240 but relations and doctor emphasise undoubted benefit from operation

his death Although there was no recurrence of his anginal pain after operation, the incapacity imposed by the trigeminal neuralgia made it impossible to test his exercise capacity

Two patients who had considerable relief from anginal pain and some increase in their exercise tolerance died five months after operation

Case 16 —This man, who was thought to have syphilitic aortitis with aortic incompetence, died in another part of the country No necropsy was done, but his doctor informed us that he seemed to be doing well and was improving gradually until four days before his death, when he developed a severe precordial pain—unlike his previous angina—which was unrelieved by nitrites and was thought at the time to be due to his aortitis

Case 20 —This man was a severe case of myocardial ischæmia who possibly abused his newly found freedom from pain and attempted too much activity His dyspnœa, but not his pain, recurred, congestive heart failure developed, and he died At necropsy gross coronary atheroma and myocardial fibrosis were found The lung, which had been encouraged to adhere to the heart after removal of part of the pericardium on the left side and smearing with aleuronat paste, was diffusely adherent, and the pericardial sac obliterated The histological records cannot now be traced

Case 27 —This similar case is that of a female private patient who enjoyed her freedom from pain following operation so much that when discharged from hospital she at once resumed full activity, despite the protestations of her medical advisers Presumably as a consequence she developed, just two months after operation, a severe precordial pain, which was diagnosed as coronary thrombosis, and died within a few hours

Case 22 —A priest, aged 57, with gross hyperpiesia (230/130) who had had severe angina for three years, became much more comfortable after grafting and resumed some of his parochial duties Two years later, however, he began to have frequent severe attacks, each one resembling a major coronary thrombosis Only slight relief from the pain of these attacks followed a left-sided sympathectomy (Raney), and he died, four years after the original operation, from cerebral thrombosis No necropsy was done, but it seems possible (to put it at its lowest) that, apart from giving some relief for two years, the presence of the graft may well explain his long survival despite the many attacks regarded as major coronary thromboses

Case 21 —This lady, now aged 75, who was grafted in 1938, is another case from which a little encouragement may be derived Although pain was never completely absent it was considerably reduced during the early postoperative years The patient however, has gross hyperpiesis (340/240) and as long ago as 1947 had albuminuric retinitis Her doctor and her family are emphatic that she has undoubtedly benefited from the operation

Cases Deriving Benefit

Although 4 of the patients in this group are now dead, the circumstances of their deaths or the dispersal of pathological material and other records unfortunately make it necessary to rely on their clinical histories for final assessment

Case 14 —A joiner and general labourer, aged 63, had had angina for nine years and latterly been unable to work. After transpleural cardio omentopexy he was freed from disability and resumed work He remained free from any symptoms

TABLE III—*continued*

Case no	Age (yr)	Sex	Duration of symptoms	Disability	Blood pressure (mm Hg)	Operation	Post operative survival	Comment
22	57	M	3 years	Severe angina precipitated by exertion heavy meals and emotion, unable to work as parish priest	230/130	June 23 1939 general anæsthesia transthoracic cardio-omentopexy graft sutured to heart	$3\frac{3}{4}$ years	Considerable relief of symptoms and resumed duty for 2 years then repeated attacks resembling severe coronary thromboses died from cerebral thrombosis, no necropsy
23	59	M	20 months	Coronary thrombosis in 1943 followed by anginal attacks on slight exertion almost confined to bed	210/130	Oct 17 1945 local followed by general anæsthesia abrasion of pericardium and insufflation of powdered asbestos (Beck)	$4\frac{1}{2}$ years +	Complete freedom from pain operated on for recurrent inguinal hernia in 1947 works as coalminer digging, and lifting girders &c
24	56	M	18 months	Coronary thrombosis followed by angina and dyspnœa on slight exertion	190/120	Dec 5 1946 general anæsthesia abrasion of pericardium and insufflation of powdered asbestos (Beck)	$3\frac{1}{2}$ years +	Free from pain and resumed work for 4 months pain and dyspnœa recurred with increasing obesity, now comparatively well after reducing weight
25	52	M	8 months	Coronary thrombosis followed by angina on exertion (2 or 3 steps) unable to work	210/130	Jan 2 1947 general anæsthesia anterior cardio omentopexy abrasion and insufflation of asbestos powder	$3\frac{1}{2}$ years +	Complete freedom from pain, can walk 7 miles runs to catch bus resumed work as colliery checkweighman
26	61	F	20 months	Angina of effort (10 yards), unable to take thyroid (required for myxœdema) without causing angina	150/100	Dec 5, 1946 general anæsthesia transthoracic cardio-omentopexy graft fixed to heart by suture and asbestos powdering	$3\frac{1}{2}$ years +	Completely freed from pain can take necessary thyroid extract and lead ordinary life
27	53	F	2 years	Angina of effort (20 yards)	120/80	June 13 1947 general anæsthesia intercostal bundle sutured to heart, pericardium abraded and insufflated with asbestos (Beck)	2 months	Complete freedom from pain resumed too much activity too quickly and died with coronary thrombosis (presumed) 2 months after operation no necropsy
28	49	M	$3\frac{1}{2}$ years	Dizziness and angina of effort (100 yards) shortness of breath almost confined to bed unable to work	102/72	Nov 24 1949 general anæsthesia anterior cardio-omentopexy omentum applied to heart abraded by asbestos powder	7 months +	Complete freedom from pain can walk 2 miles, going to Australia for holiday
29	41	M	8 months	Anginal pain brought on by exertion ($\frac{1}{4}$ mile) cold weather or heavy meals no relief by nitrites no improvement after a month s rest in bed	130/80	Jan 5 1950 general anæsthesia anterior cardio omentopexy omentum applied to heart abraded by asbestos powder	6 months +	Still has some pain on hurrying thinks he is better than before operation no dyspnœa improving, on June 27 1950 reported complete recovery anxious to resume work exercise tolerance much improved

referable to his heart for just over five years Nine years after operation he was admitted to a medical clinic, dying with abdominal symptoms, and stated that during the previous four years there had been some return of the precordial pain At necropsy a pancreatic carcinoma with many metastases was found The omentum was firmly and widely adherent to the heart and pericardium The omental vessels in it, including those apparently communicating with the heart, were extensively invaded by carcinomatous deposits Both coronary arteries were almost completely occluded by extensive calcareous changes

Case 15 —A woman, aged 47, had had angina for seven years, the attacks being usually precipitated by emotion and exertion but occasionally occurring at rest She was completely relieved of her symptoms by a transpleural cardio omentopexy and resumed full activity Four years later she was readmitted to hospital for assessment because of slight recurrence of pain and dyspnœa Unfortunately she developed sloughing pharyngitis and died from bronchopneumonia At necropsy the coronary arteries were found grossly thickened and the graft extensively adherent to the heart and pericardium

Case 4 —A brass founder, aged 51, had had angina for two years and latterly been unable to work and been virtually confined to the house After a transpleural cardio omentopexy he resumed full activity, walking up hills, working, &c, without disability Seven months later a hernial prolapse of the colon through the centre of the omentum into the chest became strangulated This remained unrecognised for forty eight hours and the patient died from paralytic ileus and bronchopneumonia five days after operation for its relief The graft was extensively adherent to the heart, and there was gross coronary atheroma, both arteries being almost obliterated

Case 6 —A man, aged 62, had had angina for twelve years and latterly been severely incapacitated After grafting of the precordial pad of fat on to the heart he was completely relieved of his symptoms and resumed ordinary activity for two years, at the end of which he died in his sleep—i e, four years after grafting

The 6 remaining patients are still alive and are even more encouraging

Case 23 —A miner, aged 59, whose blood pressure was 210/130, had had angina for twenty months following an attack of coronary thrombosis He was unable to work or to take more than two or three steps without having an anginal attack After grafting by the anterior route in October, 1945, he resumed full activity, working underground He was successfully operated on under spinal anæsthesia in April, 1947, for recurrent left inguinal hernia In a film illustrating this lecture (made in 1949) he is shown undertaking vigorous "P T," digging with pick and spade loading and wheeling a barrow, and running round a "Nylin" staircase without distress ‡

Case 11 —A miner, aged 56 with a blood pressure of 190/120, had had angina for eighteen months following an attack of coronary thrombosis Only able to walk a short distance without pain he was freed from pain and resumed work after grafting by the anterior route in December, 1946 Subsequently he became very fat from overeating and beer drinking, and after four months was readmitted to hospital with recurrence of pain and dyspnœa Those symptoms cleared on a reducing diet This has happened now on three occasions, and when last admitted, the patient was said to require constant morphinisation to control the pain, in hospital, however, it was found that injections of distilled water gave the necessary relief, and again a reducing diet and abstinence led to his discharge from hospital comparatively fit The functional element and the obesity make it difficult to assess this case but it is thought that considerable benefit has resulted from grafting

Case 12 —A miners' checkweighman aged 52, with a blood pressure of 210/130 had had angina for eight months following an attack of coronary thrombosis Almost completely incapacitated, he could only walk twenty yards without having an anginal attack After grafting by the anterior route in January, 1947, he has resumed full activity at work, he can run to catch a bus and walk seven miles He also gave the same demonstration as case 23 in a film of his exercise tolerance

Case 25 —A lady, aged 61, with a blood pressure of 150/100, had been taking thyroid tablets for myxœdema for about two years Twenty months before admission to hospital she had had an attack of what was probably coronary thrombosis after which she could neither walk more than ten yards nor take the thyroid tablets without having an anginal attack. Since a transpleural cardio omentopexy in December, 1946, she has been able to take the thyroid tablets required and resume household duties, shop, and go upstairs, &c, without discomfort She has removed to another part of the country but has written saying that she is now very well

Case 28 —A man, aged 49, with a blood pressure of 102/79 and diagnosed clinically as having aortic stenosis, had had angina and "dizzy bouts" for three and a half years. He could not work as a miner or walk on the flat for more than 100 yards, being virtually confined to bed After grafting by the anterior route in November, 1949, he is now free from pain and can walk two miles He is about to visit Australia for six months

Case 29 —A miner, aged 41, with a blood pressure of 130/80, had had angina for eight months Attacks were brought on by exertion (he could only walk a quarter of a mile without pain), cold, and heavy meals They were not relieved by nitrites or a month's rest in bed Electrocardiograms suggested definite myocardial ischæmia and possibly infarction of the anterolateral part of the left ventricle After cardio omentopexy through an anterior approach in January, 1950, the patient has improved, at first gradually but latterly to such an extent that he is now anxious to resume work. On June 27, after this lecture was delivered, he stated that he could lead a normal life Only occasionally after running does he feel anything like the old pain His exercise tolerance is much improved, he can now run round the "Nylin" staircase five times without distress

DISCUSSION OF RESULTS

A series of 30 patients operated on, of whom 11 did not survive the first month, 3 were not relieved of their angina, and 16 are thought to have benefited from grafting, including 6 in whom the relief is admittedly very problematical, may not be impressive It must be remembered, however, that nearly all the patients were cardiac derelicts for whom there was little, if any, alternative hope To restore only a third of such patients as these to full activity, even temporarily, as well as to relieve them of their painful disability seems to have been worth while Experience and better facilities for treatment now available, through development of thoracic anæsthesia and surgical methods, would almost certainly improve these results

Exact pathological proof of the efficacy of grafting in this series is lacking, but it is extremely difficult to deny that something very striking has probably happened to the myocardium in the clinically successful cases It is not unreasonable to suppose that, as in the laboratory animal and in certain of Beck's, Strieders, and O'Shaughnessy's cases, a collateral circulation has been established In view of the extreme degree of bilateral coronary disease likely to be present in comparable cases coming to necropsy, it is almost impossible to explain the clinical relief obtained solely by an improvement in the intercoronary circulation

My indebtedness must be acknowledged to Dr A G Ogilvie, consulting physician, and to Dr W G A Swan, consulting cardiologist, to the Regional Thoracic Surgery Centre, for their help with the investigation and medical management of these cases, as well as to Mr W C Barnsley, assistant surgeon, and Dr Christopher Strang, senior medical registrar, for their help in following up these cases and obtaining useful information from scattered and often inadequate records

‡ This patient had an anterior infarction in December 1950, from which he is now (February, 1951) making a good recovery

ANÆMIA OF PREGNANCY TREATED WITH INTRAVENOUS IRON

JEAN M SCOTT
M D Glasg
ASSISTANT PATHOLOGIST

A D T GOVAN
M B Glasg, Ph.D Birm, F R.F P S
DIRECTOR OF RESEARCH

GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL

SOME anæmic women attending the antenatal clinic at this hospital responded in a rather peculiar way to iron given by mouth (Scott and Govan 1949) These 14 cases (10% of our series) showed an initial rise of hæmoglobin of 2 g per 100 ml in the first month of treatment, but thereafter improvement was only slight, though treatment with iron and hydrochloric acid by mouth was continued At that time we could not explain this tendency of the hæmoglobin level to "plateau," but we pointed out that two factors were common to the group—namely, anæmia and a mild form of gastro intestinal disorder

Later (Govan and Scott 1949) we reported 25 cases of anæmia treated with intravenous iron This series included 2 cases of the above mentioned type, and both of them reacted to intravenous iron though they had not responded to iron given by mouth for three months Since then we have studied the results of treatment with intravenous iron in a larger series, including cases of this type

To date we have treated 150 patients with intravenous iron, using three proprietary preparations The biggest dose advised by the makers of two of these products is equivalent to 100 mg of elemental iron, whereas double this dose is recommended by the manufacturers of the third product

The patients formed three main groups 78 antenatal cases of uncomplicated iron deficiency anæmia, 59 cases of puerperal anæmia, and 13 antenatal cases of anæmia resistant to iron by mouth All the antenatal patients were in the last trimester of pregnancy when intravenous iron was administered

ANTENATAL IRON DEFICIENCY ANÆMIA

Of the 78 patients in this group 29 had a moderate degree of anæmia, with Hb more than 8 g per 100 ml. (average 8 9 g per 100 ml.) and 3,600,000 red cells All 29 responded to intravenous iron but not at a uniform rate 19 responded with an increase of at least 1 g (average 1 5 g) of Hb per 100 ml. at the end of the first week, after receiving the equivalent of 490 mg of elemental iron, and the remaining 10 showed an average increase of only 0.2 g of Hb per 100 ml at the end of a week During the second week these 10 patients still lagged behind the others, but by the third week their response was more satisfactory (I and II on figure)

The remaining 49 patients all had severe anæmia with an average value of 6 7 g of Hb per 100 ml and 3,590,000 red cells Of this number, 35 responded satisfactorily within a week to intravenous iron therapy with an average increase of 1 3 g of Hb per 100 ml In the following two weeks the response progressively diminished. The remaining 14 patients had a delayed response, and their hæmoglobin readings only increased by 0 3 per 100 ml during the first week, but in the second week the increase was slightly more than that shown by the other patients during the first week (III and IV on figure)

It is clear that many of the patients in this group showed a delayed response to intravenous iron, irrespective of the severity of the anæmia The plasma protein levels were estimated in all our antenatal patients, and it was found that in all the patients the plasma protein levels tended to fall as the hæmoglobin increased The fall in plasma protein level was greater in those patients who showed a delayed response At the end of treatment the plasma protein levels of the patients who responded immediately were 5 9 g per 100 ml. or more, whereas in the patients showing a delayed response the value was just over 5 g per 100 ml This fact suggests that the amount of available protein or protein reserve was limited in these cases

Daily hæmoglobin readings were made in some cases during the first week of treatment It was found that the amount of hæmoglobin tended to decrease during the first three days of treatment but thereafter increased steadily The decrease was most pronounced in severe cases Where response to treatment was delayed the fall in the hæmoglobin curve was more prolonged, and the reading at the end of seven days was often less than at the start of treatment The decrease in these cases was sometimes as much as 1 4 g per 100 ml. These changes were almost certainly the result of hæmodilution

PUERPERAL ANÆMIA

There were 59 patients in this group Only 6 had moderate anæmia (more than 8 g of Hb per 100 ml)—a number too small for analysis, and therefore they are included with the severe cases In 47 patients anæmia was the only complaint All showed an immediate and striking response to intravenous iron (V in figure) Within three weeks the average amount of hæmoglobin had increased by 5 3 g per 100 ml (1 6 g per 100 ml a week) For comparison 56 cases of uncomplicated puerperal anæmia were treated with ferrous sulphate gr 5 t.i d or ferri et ammon cit gr 30 t i d by mouth These patients also responded promptly, but, although considerable, their increase in hæmoglobin was not comparable with that obtained with intravenous iron At the end of four weeks the average increase of hæmoglobin was 3 4 g per 100 ml (0 8 g per a week)

The remaining 12 patients all had severe anæmia complicated by some other factor 7 of them had had severe shock at delivery, from placenta prævia, retained placenta, cervical lacerations, or cæsarean section, 4 had a secondary puerperal infection, and 1 was a grade IV cardiac In all these cases the response to treatment was delayed, and during the first week of treatment the average increase of hæmoglobin was only 0 3 g per 100 ml. During subsequent weeks, however, the response was similar to that of the other patients (VI in figure)

ANÆMIA RESISTANT TO IRON BY MOUTH

In this group 13 patients received iron and hydrochloric acid by mouth for one to five months (average

Responses to intravenous iron I Immediate in 19 cases of moderate anæmia. II: delayed in 10 cases of moderate anæmia. III Immediate in 35 cases of severe anæmia. IV: delayed in 14 cases of severe anæmia V In 49 cases of puerperal anæmia VI: in 12 cases of puerperal anæmia complicated by some other condition

2 4 months) Of these 5 had moderate anæmia and 8 severe anæmia, the average hæmoglobin reading being 7 5 g per 100 ml After treatment the average hæmoglobin value had only increased to 7 8 g per 100 ml The peripheral blood picture was still that of a microcytic hypochromic anæmia The plasma protein level averaged 5 5 g per 100 ml Test meals on 4 of these patients showed achlorhydria Marrow biopsy was also performed, but there was no evidence of pernicious anæmia, although the picture is one which appears to be diagnostic of this type of anæmia (unpublished work) Intravenous iron produced an immediate response in 11 cases, the hæmoglobin rising 1 2 g per 100 ml in the first week In the remaining 2 cases improvement was delayed, but during the second week of treatment the hæmoglobin rose by 1 9 g and 2 1 g per 100 ml respectively

The average increase of hæmoglobin for the whole group during the first week was 1 2 g per 100 ml and in the second week 1 g per 100 ml

DOSAGE

In general we have adopted the following regime On the first day the equivalent of 30 mg of elemental iron is given, on the second day 60 mg, and on the third day 100 mg Thereafter 100 mg is given daily until the end of the first week During the second week 100 mg is given every second day, so that by the end of this week 790 mg of elemental iron has been given This is sufficient to raise the "moderate" cases above the anæmia level, and they may then be given iron by mouth if necessary Patients with severe anæmia may continue with intravenous iron 100 mg every second day in subsequent weeks, or the dose may be reduced to 100 mg once a week according to the severity of the anæmia

We have been unable to use larger doses than 100 mg of any of the three products, because of the frequency of reactions when that figure is exceeded

REACTIONS

Minor reactions, such as pain in the arm, are fairly common, occurring in about 20% of cases This reaction seems to be common to many types of intravenous injection and is not specifically due to iron The most alarming reaction in pregnant women only occurs in about 1 or 2% of cases, and takes the form of a vaso vagal attack, which we have described previously (Govan and Scott 1949) This type of reaction appears in some cases to depend on the amount of iron given in a single injection It occurred in a few patients to whom we attempted to give more than the usual dose of 100 mg of elemental iron It may be seen, however, in some patients even with the usual dosage In these cases its occurrence is irregular and does not follow any particular number of injections, but seems to be related more to the patient's condition at the time of injection We have investigated some of these cases and hope to report on them later

UTILISATION OF IRON BY PREGNANT PATIENT

According to many workers—e g, Heath et al (1932), Goetsch et al (1946), and Nissim (1947)—intravenous iron is used quantitatively by the non pregnant anæmic patient, the hæmoglobin increasing by 4% for every 100 mg of elemental iron injected We have shown that during pregnancy the average increase in hæmoglobin per 100 mg of elemental iron is about half that —i e, 0 3 g per 100 ml It has always been assumed that there is a considerable maternal storage during the early part of pregnancy, and that during the later months there is deviation of iron to the fœtus We have previously suggested (Govan and Scott 1949) that the difference between the figures cited above, which is very considerable, was the result of maternal storage or transport of the iron to the fœtus

We have investigated this point and, although our work is still in the preliminary stages, it is possible to make a definite statement indicating that maternal storage and fœtal demands are not entirely responsible for the limited response of the anæmic pregnant patients to intravenous iron Serial estimations of serum iron level were made following the injection of 100 mg of iron, and in the average case the plotted values formed a steep curve Ten minutes after injection the serum iron level rose from 95 µg per 100 ml to about 325 µg per 100 ml, but an almost equally rapid fall took place within the next two hours It seemed to us that the iron was disappearing too quickly from the serum to be explained on the basis of storage, and the urine was found to contain iron In this particular instance the specimen of urine passed two hours after injection contained 2 6 mg of iron In the twenty four hours following injection 5 2 mg of iron was excreted. The urine was collected in acid washed china containers, and no specimen passed with fæces was included Before estimation the urine was passed through acid washed filter papers It was next digested with concentrated sulphuric acid, and the iron was titrated in the usual way with thiocyanate

Urine from 10 normal controls and from untreated patients with anæmia gave negative results Up to now we have found that iron does not always appear in the urine after the initial injections but that it regularly appears later in the course of therapy In 2 cases of anæmia in non pregnant patients iron appeared in the urine after intravenous therapy, and we have also found it in the urine of puerperal cases undergoing treatment

DISCUSSION

Our previous findings (Govan and Scott 1949) have been confirmed Intravenous iron therapy is a useful means of treatment of anæmia in pregnancy, especially when time is short It is apparent, however, in this extended series that all cases of iron deficiency anæmia do not respond in the same way Most of the patients respond rapidly, and in moderate anæmia the hæmoglobin is increased in the first week by 1 5 g per 100 ml on the average, whereas in severe cases the increase is 1 3 g per 100 ml These figures compare fairly well with that of 1 3 g per 100 ml reported in our first series. The difference of 0 2 g per 100 ml between the response of moderate and that of severe anæmia was puzzling until we examined the hæmoglobin level daily In all degrees of anæmia iron therapy seems to initiate hæmodilution, which, however, is more severe and lasts longer in severe cases This causes a fall in hæmoglobin percentage and obscures the response to treatment Hæmodilution is most important in the puerperium, when there are fairly rapid and well marked changes in blood volume which may mislead the observer in making a diagnosis and assessing treatment

Delay in response until the second week of treatment was noted in 34 5% of moderate cases and 40% of severe cases No difference was detected between the blood or marrow pictures of the patients who responded immediately and of those in whom the response was delayed, but in the latter patients the plasma protein levels were uniformly low at the end of treatment Superficially at least this suggests that the delay in hæmoglobin regeneration may be related to the availability of protein In this respect it is interesting to note that Hahn and Whipple (1939) have found that the rate of hæmoglobin regeneration in anæmic animals is influenced by the intake of dietary protein

In the puerperium the response to intravenous iron is even greater than in the antenatal period It has been shown by many workers—e g , Heath et al (1932), Goetsch et al (1946), and Nissim (1947)—that intravenous iron is used quantitatively by non pregnant women, 100 mg of elemental iron leading to an increase of hæmoglobin of 4% (0 6 g Haldane) The highest response in our antenatal series was 0 4 g per 100 mg of elemental iron (average 0 3 g) In postnatal cases, however, the average hæmoglobin increase per 100 mg of elemental iron was 0 6 g , the highest individual response being 0 8 g per 100 mg The last named figure represents an abnormal increase, but it is more apparent then real, since the gradual hæmoconcentration starting about the third day of the puerperium must be taken into consideration (Crawford 1940) The same applies to the pronounced increase in the average hæmoglobin, 2 1 g per 100 ml., during the first week of treatment The calculated hæmoglobin increase of 0 6 g per 100 mg of iron during the puerperium is therefore probably greater than the actual, and it seems that even puerperal patients do not use the injected iron quantitatively

It will be noted that some puerperal patients did not respond immediately to treatment In 5 cases the cause was infection and cardiac failure The remainder had all suffered severe shock at delivery , this condition seems to depress the response to intravenous iron for a considerable time after delivery Although hæmorrhage initiated the shock in some of these cases, the delay in response was not due to blood loss, because many of the patients who responded normally had lost a considerable quantity of blood but none had suffered shock

Cases of anæmia resistant to iron given by mouth are comparatively common during pregnancy The number of such cases in our series is unknown, because most of the patients were treated with intravenous iron from the start The 13 cases we report here, however, are typical Achlorhydria was present in every case we examined, but routine treatment with dilute hydrochloric acid made no difference to their response to iron by mouth, and it seems very unlikely that a simple lack of acid could be the sole factor responsible According to Granick (1946) iron combines with apoferritin in the intestinal mucosa to form ferritin Thereafter the iron diffuses into the plasma, where it is probably linked with globulin Copp and Greenberg (1946) have shown that the diffusion of iron into the plasma is inversely proportional to the serum iron level and ceases when a certain saturation point is reached Repeated serum iron estimations were made in 3 of our patients receiving iron by mouth The results were uniformly low, varying from 5 to 45 µg per 100 ml. There was therefore no question of saturation of the plasma with iron in these cases

A possibility which must be considered is the availability of protein for the transport of iron In these cases, however, the plasma protein levels were relatively high and the serum iron level was low, and all the patients reacted to intravenous iron It seems likely that lack of response to iron by mouth is entirely related to the absorptive mechanism in the intestine Whether the intestinal environment is such that the iron is transformed into some compound which is incapable of being absorbed or the more intimate mechanism involving the apoferritin ferritin complex is upset is not known

Our finding of iron in the urine after intravenous therapy raises a number of interesting problems If, as seems likely, the iron is derived from the material injected, it would appear that either the capacity of these patients to deal with injected iron is limited or a renal threshold exists above which iron enters the urine It remains to be seen whether this urinary excretion is related to the modified response of these patients to intravenous iron It is just possible that the urinary iron is derived from some source other than the material injected However, the finding of iron in the urine of patients in the puerperium and of non pregnant patients undergoing treatment indicates that some revaluation of this mode of therapy is required

According to Hahn (1937), iron is only excreted in the urine in insignificant amounts in normal conditions A similar statement has been made by Barer and Fowler (1937) Cartwright (1946) states that only 1 5% at most of the original intravenous dose is excreted by the kidneys Most workers seem to assume that iron is never excreted in the urine after any mode of administration Our findings are in direct contrast to this, and we have even found iron in the urine of two patients undergoing treatment with iron by mouth

SUMMARY

The results of intravenous iron therapy in 150 cases of anæmia of pregnancy and the puerperium are recorded

During the antenatal period most of the cases responded immediately, and with the dosage used there was an average increase of 1 5 g of hæmoglobin per 100 ml in a week

About a third of the patients showed a delay in response until the second week of treatment This delay seemed to be related to the availability of protein

During the later months of pregnancy the highest response increase of hæmoglobin was 0 4 g per 100 mg of elemental iron

Treatment with intravenous iron at this period induced a temporary hæmodilution lasting three days in moderate anæmia and four or more days in severe anæmia

During the puerperium the average response to intravenous iron almost reached the calculated level of 4% per 100 mg of elemental iron In a few cases this figure might be exceeded, probably owing to the normal hæmoconcentration which begins usually about the third day after delivery

Response was delayed in the puerperium in infections, in systemic diseases, and in patients who had suffered shock at delivery

Iron deficiency anæmia which had proved resistant to iron by mouth improved rapidly under intravenous therapy The possible causes of resistance to oral iron are discussed

A dosage scheme is given, and it is recommended that in the treatment of anæmia of pregnancy no single dose should exceed 100 mg of elemental iron Severe reactions tend to develop when higher doses than this are given

Iron appears in the urine after intravenous injection This may be partly responsible for the modified response to intravenous iron during pregnancy

INCIDENCE OF TUBERCULIN SENSITIVITY IN HOSPITAL CHILDREN

RELATED MORTALITY

MARGUERITE J LUNN
M B Glasg

From the Department of Child Health, University of Glasgow, and the Royal Hospital for Sick Children, Glasgow

A GREAT deal has been written about the incidence of tuberculosis in adults, but less is known of the frequency of tuberculous infection in children, as Miller (1949) has recently pointed out Watkins (1945) found that the tuberculin sensitivity rate in the medical unit of a children's hospital in Cardiff was in the region of 22% , but the unit did not admit known cases of tuberculosis, and tuberculin skin tests were performed only in selected cases Thompson (1947) reported on children in the Acton and Ealing districts of London who were tested in 1942–45 , but here too the series was not representative, since the children were attending tuberculosis clinics because of suspected infection or as contacts In 66 2% of the contact group, and 49 6% of the others there was a positive reaction to tuberculin jelly or to intradermal tuberculin

Brieger (1943) quotes the results obtained by Stott in the Papworth children, using the Moro test The reaction was positive in 63% of the children in their second year of life and in 56 8% of those aged one to five years Brieger also quotes some Continental observations For example, Heynsius van den Berg (1936) in Holland found that 71 5% of children under one year of age in contact with open tuberculosis were infected, the rate varying from 31 2%, under good hygienic conditions with slight exposure, to 100% under bad hygienic conditions with massive exposure. In Germany Seiffert (1935) reported that of children under five years of age who had been exposed to infectious tuberculosis 71 6–79 3% gave a positive reaction At the Royal Hospital for Sick Children, Glasgow, of 1470 children up to thirteen years old admitted to one medical unit in the years 1948 and 1949 116 gave a history of contact with open tuberculosis, and 68 of these proved to be tuberculin positive That is to say, 58% of these contacts had become sensitised

The following observations are presented to give an indication of the incidence of tuberculous infection, as measured by tuberculin sensitivity, in all children from birth to thirteen years admitted to the wards of one medical unit of the Royal Hospital for Sick Children, Glasgow, over the ten year period 1940–49 As no selection was exercised, the field surveyed is distinctly wider than in the above reports It must be emphasised, however, that these children do not represent a cross section of the juvenile population of Glasgow, or even of any one of its social classes The findings relate only to those admitted to a general children's hospital suffering from medical diseases

MATERIAL AND METHODS

Cutaneous sensitivity to tuberculoprotein was first demonstrated by Pirquet in 1907 It can be taken as evidence of infection with tubercle bacilli, and provides the best means of estimating the incidence of such infection in children

In the medical unit concerned, all children, except infants under four weeks of age, are on admission subjected, as a matter of routine, to two different tuberculin skin tests From 1940 to 1945, the Mantoux and the Pirquet tests were used, but after 1945 the latter was replaced by the tuberculin jelly test The figures presented here are based entirely on the results of the Mantoux intradermal reaction, because this is generally accepted as the most reliable of all the tests for tuberculin sensitivity (Hart 1932) No attempt is made to compare the merits of the various tests

In performing the Mantoux test, a weal was produced by the intradermal injection on the forearm of 0 1 ml. of a dilution of Old Tuberculin, fresh solutions being prepared every two weeks A 1/5000 solution was used for the first test, followed by a 1/1000 solution if the first test was negative and tuberculous disease was suspected clinically, and by injection of a 1/100 solution if the reaction was still doubtful The result of each test was read twenty four and forty-eight hours later It was assessed in most cases by two independent observers, erythema and induration both being required for a positive result The precise extent of the erythema and induration were not recorded, but broadly speaking the result was regarded as positive when the diameter of the reaction was 10 mm or more, and doubtful or negative when it was less than 10 mm

Changes in the staff performing and reading the tests have been unavoidable during the ten year period, and the different batches of tuberculin used must obviously have varied in potency , but these are variations which must occur in any large unselected series extending over a number of years

RESULTS

Annual Incidence

In the period 1940–49 7555 children were admitted to the unit Of these 1071 (14 7%) were Mantoux positive and 5175 (68 5%) were Mantoux negative (table I) The remaining 1309 (17 3%) comprise a group in which no results are available It consists of newborn and young infants on whom skin tests were not performed , some children who were allowed home, or transferred to a fever hospital, before their skin tests were due to be read , some who died within forty eight hours of admission , and a few in whom the results of the test were equivocal This group entitled " results not available " is included in the table because the figures are intended to show the incidence of tuberculin sensitivity in all the patients admitted to the unit It must be pointed out, however, that 1074 of the 1309 children in this group were under one year of age, and 83% of these were under three months It may be assumed that the tuberculin sensitivity rate at this age

TABLE I—RESULTS OF MANTOUX TESTS (YEARLY)

Year	Total admissions	Positive reactors	Negative reactors	' Results not available '
1940	683	95 (*14 0%*)	470 (*68 1%*)	118 (*17 3%*)

TABLE II—RESULTS OF MANTOUX TESTS (AGE GROUPS)

Age (years)	Total admissions	Positive reactors	Negative reactors	Results not available
0–1	3395	79 (2 3%)	2242 (66 0%)	1074 (31 6%)
1–2	900	112 (12 4%)	738 (82 0%)	50 (5 6%)
2–3	589	93 (15 8%)	458 (77 8%)	38 (6 4%)
3–4	413	75 (18 2%)	318 (77 0%)	20 (4 8%)
4–5	321	79 (24 6%)	222 (69 2%)	20 (6 2%)
5–6	335	86 (25 7%)	234 (69 9%)	15 (4 5%)
6–7	282	77 (27 3%)	193 (68 4%)	12 (4 3%)
7–8	277	83 (30 0%)	173 (62 5%)	21 (7 5%)
8–9	250	76 (30 4%)	160 (64 0%)	14 (5 6%)
9–10	227	80 (35 2%)	136 (59 9%)	11 (4 8%)
10–11	248	91 (36 7%)	143 (57 7%)	14 (5 6%)
11–12	196	89 (45 4%)	98 (50 1%)	9 (4 6%)
12–13	122	51 (41 8%)	60 (49 2%)	11 (8 9%)
Totals	7555	1071 (14 7%)	5175 (68 5%)	1309 (17 3%)

is very low, so no attempt has been made to introduce a correction in respect of these children

The incidence of positive reactors varies from year to year, the lowest was 10 2% in 1944, and the highest 20 3% in 1948 It is perhaps more significant that in 1940 it was 13 9% of all admissions, and by 1949 it was still at the same level Thus the incidence apparently did not rise during the ten years

A feature of the annual incidence is the relatively high level in 1946 (18 3%) and 1948 (20 3%) This is difficult to explain It might be suggested that the advent of streptomycin brought more tuberculous children to hospital, but this is ruled out by the fact that in 1947, the year between the two peaks, the rate was normal (13 4%). Nor does the incidence correspond to that of adult respiratory tuberculosis in Glasgow, which began to rise during the war and reached its peak in 1947 On the other hand, whereas in 1940 a family history of tuberculosis was obtained in only 20% of the positive reactors, in 1949 this figure had risen to 42 3%

Age incidence

Table II shows the number of positive reactors in each year of life from birth to thirteen years As one would expect, the percentage increases with age, but when the 12–13 age group is reached it unexpectedly falls This is most easily explained by saying that because the total number of admissions in the 12–13 age group is relatively small it may not be a representative sample Another factor, however, is the slightly higher proportion among them of "results not available," which makes the percentage of both negative and positive reactors lower than in the preceding age group

Mantoux Reversion

It is now universally accepted that Mantoux reversion does occur, and in the Prophit Survey Report Daniels et al. (1948) think it important enough to modify considerably the incidence of tuberculin sensitivity in a given community Lloyd and MacPherson (1933), in 303 urban children, found a reversion rate of 2% after an interval of two years Horan (1935) found a reversion-rate of 14% after eighteen months in 197 schoolboys aged fourteen and fifteen years Keller and Kampmeier (1939), working with students, found that 21% had reverted after four years Dahlström (1940) reported a reversion rate of 11 1% among 2828 persons after periods of five to fifteen years Madsen et al (1942) noted the influence of bovine tuberculosis on the reversion rate in 1000 Danish school-children In districts where there was a great deal of tuberculosis among cattle the rate was only 0 3%, whereas in districts where the cattle were free from tuberculosis it was 3%

In this country the phenomenon of reversion has received little attention, from which it may be inferred that it is not regarded as important But reversion may well be growing commoner now that tuberculin testing of cattle and pasteurisation of milk are eliminating the intermittent sensitivity sustaining doses of bovine tubercle bacilli in milk The theory that repeated small doses of tubercle bacilli are responsible for the persistence of allergy is supported by the work of Dahlström (1940) who found that reversion was commonest in families whose members had been least exposed to tuberculosis, and became less common as the probable exposure to tuberculosis increased On the other hand Crimm and Short (1939) were impressed by the number of patients who lost their allergy despite continued contact with tuberculosis, and suggested that desensitisation might result from "frequent subreactionary doses of tubercle bacilli"

In a small series of 40 children re tested at the Royal Hospital for Sick Children three to ten years after a known positive reaction, 6 were negative to 1/100 tuberculin This series is too small to be significant but the subject obviously requires further investigation The question also arises whether Mantoux reversion indicates bacteriological healing of the primary lesion, just as calcification is taken to indicate clinical healing, and it would be of interest to attempt to correlate calcification and the subsequent resorption of calcium with loss of cutaneous tuberculin sensitivity

Mantoux reversion probably reduces to some extent the tuberculin sensitivity rate in the older age groups, but until it is more fully understood no further conclusions can be drawn

Negative Reactors Among Tuberculous Children

Some observations have been made on another well recognised group of children—those who remain Mantoux negative despite conclusive evidence of active tuberculosis During the ten year period under survey, 37 such children were seen They were all suffering from acute progressive tuberculosis, diagnosed clinically and radiologically or bacteriologically, or confirmed at necropsy, and at the time of skin testing were in an advanced stage of the disease Of these 37, 33 died during their stay in hospital, 2 were transferred to other hospitals for streptomycin therapy, and 2, with tuberculous peritonitis, survived and were allowed home

The ages of these children ranged from five months to ten years and reflected the usual high death rate in children under three years 21 of them had not reached their third birthday when they developed fulminating tuberculosis from which they died The types of lesions in these 37 Mantoux negative children were

Tuberculous meningitis	27
Miliary tuberculosis	3
Tuberculous bronchopneumonia	4
Tuberculous peritonitis	2
Spinal caries and meningitis	1
Total	37

Whether or not these children were at any stage of their illness sensitive to tuberculoprotein we do not know, but it seems more likely that the original dose of bacilli was so massive, and the organism so virulent, that they did not have the opportunity to develop sensitivity They also failed to develop the immunity required to localise the disease process

Mortality Related to Age

Table III shows the deaths from tuberculosis in hospital during the ten year period it also includes a few children discharged home with tuberculous meningitis The total number of deaths was 251, or 22 7% of the whole group of "infected children" which comprises positive reactors, children dying of tuberculosis within forty eight hours of admission to hospital, and the 37 Mantoux negative children referred to above who had acute progressive tuberculosis without tuberculin sensitivity

TABLE III—TUBERCULOSIS DEATHS (AGE GROUPS)

Age (years)	"Infected children"	Deaths	Percentage deaths of infected children
0–1	87	54	62
1–2	117	58	50
2–3	101	37	37
3–4	81	32	39
4–5	81	15	18
5–6	87	14	16
6–7	79	7	9
7–8	86	13	15
8–9	70	5	7
9–10	81	8	10
10–11	92	5	5
11–12	89	1	1
12–13	51	2	4
Totals	1108	251	22 7

"Infected children comprises those who were (a) Mantoux positive (b) tuberculous but Mantoux negative (c) tuberculous and dying within forty-eight hours of admission

The number of deaths in hospital does not of course represent the total number of deaths from tuberculosis in these children, a late follow up of whom is now in progress Most children, however, with evidence of a recent primary infection were watched for several months at least after discharge Wallgren (1943) found that the danger period in childhood lies between the fourth and twelfth weeks after the development of tuberculin sensitivity, and it might therefore be assumed that there were only a few deaths subsequently Nevertheless, the fact remains that the mortality rate of 22 7% bears no relation to the mortality from childhood tuberculosis in general, and depends entirely on the type of case admitted to this unit

Table III shows that the mortality is highest, by far, during the first year of life, when 62% of the cases prove fatal, but this high figure falls off rapidly, particularly between the third and fourth years, when it is reduced to less than half This is in keeping with the usual belief that meningitis is more likely to occur in children infected during the first three years of life than in those infected later Of the 251 deaths occurring in hospital during the ten year period, 88% showed evidence of meningitis This preponderance of meningitis over all other lesions in the fatal cases obtains at all ages above six months, below that age, meningitis was present in only 8 of 19 cases Far behind meningitis come bronchopneumonia (13 cases), miliary tuberculosis without meningitis (8), peritonitis (4), tuberculomata (2), and enteritis (1)

SUMMARY

A survey has been made of the tuberculin sensitivity of all children from birth to thirteen years of age admitted to the wards of a medical unit of a children's hospital in the ten years 1940–49

The proportion of positive reactors varied from 10 2% in 1944 to 20 3% in 1948 (average 14 2%)

The tuberculin sensitivity rate in different age groups is shown, starting at 2 4% in the 0–1 year age group and rising to 41 8% in the age group 12–13 Mantoux reversion occurred in 6 of 40 cases which were followed up There were 37 cases of tuberculosis in Mantoux-negative children

The mortality from tuberculosis in the various age groups is shown It varied from 62% in infected infants under one year to about 5% in the higher age groups The greatest reduction in mortality occurred between the third and fourth years The average mortality rate in all age groups of infected children in hospital was 22 7%

The various tuberculous lesions responsible for death are enumerated, evidence of meningitis was present in 88% of the children dying of tuberculosis.

I wish to express my thanks to Prof Stanley Graham for permission to use the case records of his unit in the Royal Hospital for Sick Children, and for his encouragement and advice during the preparation of this paper The work was done during tenure of the Walter K Hunter Research Fellowship in Medical Diseases of Children

BLEGDAMS HOSPITAL, COPENHAGEN

IN the last few years many clinically important conditions have been described in which there is an acute or at any rate transitory lack of potassium on the blood serum (these are well reviewed by Danowski 1949) Chronic persistent hypokalæmia, however, has only occasionally been reported (Albright and Reifenstein 1948) Hadorn (1948) described a case of osteomalacia complicated by a tendency to œdema and by hypokalæmia, which slowly recovered spontaneously

The present case is reported because the patient was found to need permanent potassium therapy

CASE RECORD

A married woman, aged 33, was transferred to the medical department from the surgical wards on Oct 4 1948 because she had had two severe heart attacks accompanied by collapse with muscular weakness and hypotension. There was no history of familial muscular paralysis The patient had been healthy as a child, menstruation had begun at the age of 15, and apart from a year's amenorrhœa when she was 18 had been regular until 1945 She had had three normal pregnancies, in 1938, 1940, and 1945, and her children were healthy In August 1943, she had had a brief feverish illness accompanied by neck stiffness and extensor plantar reflexes, which was diagnosed as lymphocytic meningitis because there was an epidemic of such cases at the time, though the patient had not been investigated Since then, at regular monthly intervals starting about fourteen days before menstruation she had become generally œdematous, without any albuminuria, and these attacks had been treated with mercurial diuretics Since her delivery in 1946 she had not menstruated but the œdema had appeared as before, so that she was having about a fortnight with œdema and then about a fortnight without Gynæcological examination revealed only slight genital hypoplasia

In February, 1948, the patient became pregnant again, and in the early months of this pregnancy her periodic œdema ceased for the first time In June, the fifth month of her pregnancy, she had peritonsillitis, which was treated at home with penicillin. This was followed by severe anorexia, dehydration, and loss of weight and energy On July 16 she went into labour and was admitted to hospital where she gave birth to a stillborn female fœtus weighing 2 lb After delivery her temperature was at first subnormal, after which it rose to slightly above normal and remained so for some weeks During this period various signs and

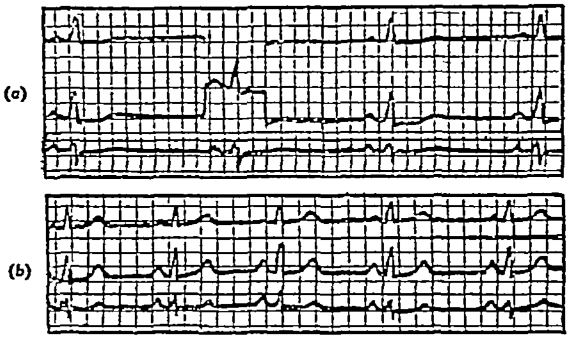

Fig. 1—Electrocardiogram (a) during period of severe potassium deficiency and (b) after treatment with potassium phosphate by mouth

symptoms which had been present since her delivery became accentuated these were hypotension, bradycardia severe thirst, diuresis muscular weakness a feeling of extreme tiredness, paræsthesiæ, and a fall in weight from 8 st $2^1/_2$ lb to 6 st $5^1/_2$ lb Her excretion of 17 ketosteroids mineralo-steroids and glucocortico steroids was abnormally low, and there was no demonstrable excretion of gonadotropic and œstrogenic hormones Electromyography and serum acetyl choline were normal

Her condition was interpreted as the onset of a crisis in Addison s disease, and she was therefore given intramuscular injections of 10 mg of deoxycortone acetate ('Percorten,' Ciba) daily for ten days, after which she had two or three severe heart attacks, with an irregular rapid heart-beat and a feeling of anxiety The last attack occurred an hour after she had received a litre of physiological saline with 5% glucose intravenously she collapsed, with imperceptible pulse and respirations for $1^1/_2$ min. Her serum potassium level was found to be seriously low (1 38 m eq per litre) and she was transferred to the medical department

Condition on Admission to Medical Wards—There was pronounced prostration. She was emaciated (weight 6 st 8 lb, height 5 ft. 3 in.), her skin was dry but not abnormally pigmented and her hair distribution was normal There was extreme muscular weakness, so that she could not lift her outstretched legs from the bed No further abnormality was found on clinical examination and the optic discs and central nervous system were normal In the laboratory findings (see table) the only abnormality was a pronounced hypokalæmia (2 m.eq per litre) and a low serum chloride level The urea clearance was 30 and 24 c cm, and diuresis 1 12 and 0 72 ml per min (After potassium therapy the urea clearance was 75 and diuresis 3 4 ml per min.) Electrocardiography on numerous occasions showed changes characteristic of hypokalæmia (fig 1) The X ray appearances of the cranium, lungs, and urinary tract were normal

Progress—A few days after her admission the patient became œdematous, she said that the œdema was less than she had formerly but was of the same type It disappeared quickly and spontaneously In the next few months the patient was free from symptoms, except for anorexia, general weakness, and amenorrhœa Her serum potassium was persistently low (about 2 5 m.eq per litre) Since it was thought that the hypokalæmia *might* be a sequel *to* the treatment with deoxycortone potassium therapy was postponed for six months to see if there would be a spontaneous remission and it seemed certain that by then the deoxycortone injected would have been eliminated (see fig 3) During these six months the patient was kept in bed on an adequate, varied, and appetising diet and her condition improved slightly as her appetite increased she gained 5 lb in weight and her tiredness and weakness waned a little though she could still get out of bed only with difficulty and for short periods

Fig 2—Electrocardiographic changes during administration of potassium The amount of potassium excreted in the *urine* in the first twenty-four hours was 1·69 g Potassium phosphate (15 g of potassium) was given by mouth at 0 hr

Potassium Treatment—Potassium was given for the first time on March 22, 1949 when the patient s serum potassium was 2 84 m eq per litre After 15 g of potassium, in the form of neutral potassium phosphate (KH_2PO_4, 52 4 g K_2HPO_4, 33 5 g water to 300 g) had been given by mouth, her serum potassium rose to 4 9 m.eq per litre in three hours (see fig 2) The potassium had a powerful *effect* producing transient palpitations and later a temporary collapse, with a suggestion of tetany in the position of the fingers The considerable quantity of phosphate which this solution contained caused a fall in serum-calcium In the next twenty-four hours only 1 69 g of potassium and 0 04 g of sodium was excreted in the urine The neutral potassium phosphate solution by mouth was continued in the dosage shown in fig 3 In the subsequent period a considerable retention of potassium was demonstrated—more than 87% (2 7 g a day) of the potassium phosphate given, over and above the potassium in her food, was retained After ten days' treatment her *serum potassium* was 5 13 m eq per litre, and the proportion of the potassium retained in a three-day period was 96% (2 9 g a day) Excretion of sodium remained abnormally low (0·02–0 83 g a day) When the patient s serum potassium had become normal, the dose was reduced to 1 5 g of potassium a day (neutral potassium phosphate solution 15 ml in one daily dose) In addition 0 8 g of sodium (2 g of sodium

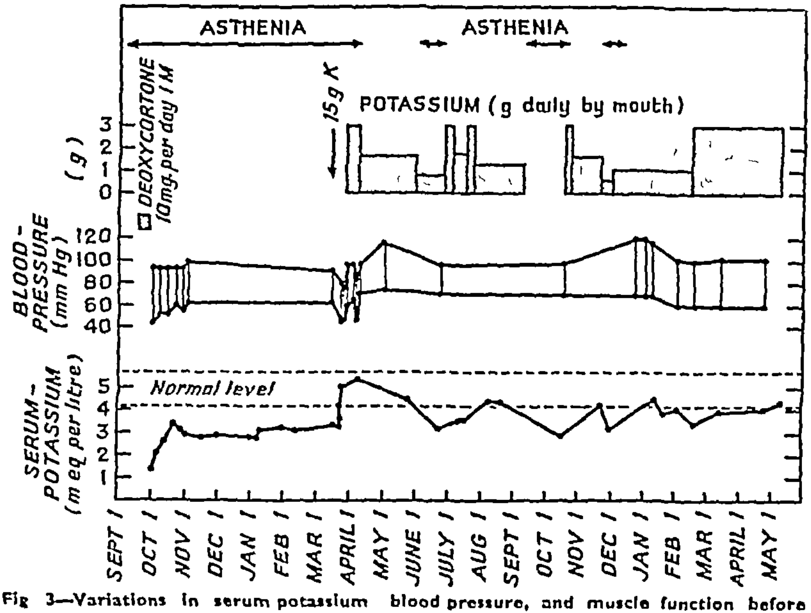

Fig 3—Variations in serum potassium blood pressure, and muscle function before and after treatment with potassium phosphate by mouth

chloride) was given daily It had been observed previously that the patient s cyclic œdema was independent of her intake of sodium chloride Thereafter her serum potassium remained subnormal or normal, and her serum sodium was 133 m eq per litre (see fig 3) The average volume of urine excreted over a three day period was 1720 ml , with a daily excretion of 3 g of potassium and 0 6 g of sodium The patient's appearance and general condition improved strikingly in this period, and she was discharged feeling reasonably well on April 15, 1949 Her tiredness and weakness had disappeared menstruation was normal, and she resumed her work

Course after Discharge —On June 1 the patient of her own accord reduced her daily dose to 0 5 g of potassium (5 ml of the solution), and after this she became worse and her serum potassium fell The dose was therefore increased (fig 4) whereupon her symptoms again disappeared

On Aug 16 her serum potassium was 4 07 m eq per litre and her electrocardiogram still normal On her own initiative she stopped her potassium altogether on Sept 10, because she felt completely well A few days later she felt tired and weak and had palpitations On Oct 14 her serum potassium was 2 76 m eq and her serum sodium 134 m eq per litre When she resumed her treatment she recovered completely in a few days At the end of November she again experimented by halving her daily dose, taking 0 5 instead of 1 g of potassium Her health gradually deteriorated, and her serum potassium fell to 3 06 m eq per litre The previous dosage of potassium had to be resumed and again she fully and rapidly recovered Her tendency to intermittent œdema and retention of fluid, with increase in weight, particularly before menstruation, did not seem to be affected by the therapeutic intake of potassium (see fig 4) A glucose tolerance test with 25 g of glucose by mouth gave the characteristic fall in serum potassium but did not produce pareses such as occur in familial muscular paralysis (fig 5) After two months, during which she regularly took 3 g of potassium daily by mouth, her average daily excretion of urine over a three-day period was 2267 ml , containing 5 65 g of potassium and 2 70 g of sodium daily

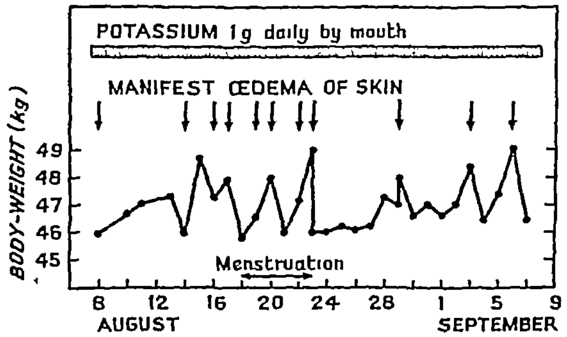

Fig 4—Variations in fluid content of body in relation to changes

The potassium treatment has been continued since January, 1950, with a neutral *aqueous solution of potassium* salts containing KH_2PO_4 45 g , K_2HPO_4 45 g , and KCl 130 g., in a litre of distilled water Each 10 ml. of this solution contains potassium 1 g (25 0 m eq), phosphorus 0 18 g (8 5 m.eq of PO_4), and chloride 0 62 g (17 4 m eq)

DISCUSSION

It seems clear that this patient cannot maintain the normal level of potassium in her extracellular fluid without a regular supplementary intake of potassium The reason for this is obscure Theoretically, such a defect might arise (1) in the kidneys, where there might be a reduced reabsorption of filtered potassium and/or increased tubular excretion of potassium, (2) in the muscles, if they were not assimilating potassium in the normal way, as happens in *familial muscular paralysis*, or (3) in the hypothalamus, where the chemosensitive electrolyte regulating centres might be insufficiently sensitive to the plasma potassium level.

The considerable retention of potassium that followed its administration by mouth points away from loss through the kidneys as the cause of the hypokalæmia, but it suggests that a lack of intracellular potassium deficiency is an essential factor in her condition In *this respect the case* resembles familial muscular paralysis, *in which Danowski* et al (1948) found that the muscle potassium was deficient and that the paralysis could be relieved by suddenly reducing the potassium *level in* the *extracellular* fluid—e g , by increasing the intake of glucose The present patient, however, never had any acute attacks of paresis

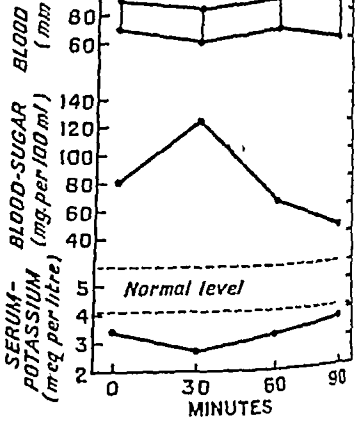

Fig 5—Glucose-tolerance test. Note absence of paresis and of any dangerous fall in blood pressure during the accentuated hypokalæmia.

A disturbance of central regulation seems the most likely explanation, and this might have arisen from the patient's lymphocytic meningitis some years before

For the present the patient's chronic potassium deficiency *must* be classed as cryptogenic, but it is important to recognise that such cases exist, that the condition may be hard to differentiate from Addison's disease, anorexia nervosa, and familial periodic muscular paralysis , and that potassium phosphate by mouth will relieve all the symptoms of hypokalæmia *over* long periods and may be life saving

SUMMARY

A woman of 33, who had had lymphocytic meningitis five years *before*, developed severe anorexia and muscular weakness after an attack of peritonsillitis and a six-month abortion She was at first thought to have Addison's disease, but treatment with sodium chloride and deoxycortone produced severe cardiac disturbances and she was then found to have a very low serum-potassium level.

Her hypokalæmia and weakness lasted for six months and could only be relieved by giving potassium phosphate regularly by mouth, her condition relapsing whenever the potassium therapy was discontinued.

BLEGDAMS HOSPITAL, COPENHAGEN

In the hope of throwing some light on the treatment of patients with severe potassium deficiency we are reporting the following case of chronic renal hypokalæmia, with the blood-electrolyte findings during several forms of potassium therapy Some studies of the inter relation of serum electrolytes in rabbits are also described.

CASE-RECORD

A married woman, aged 44, was admitted on Oct 1 1949 to Blegdams Hospital with several days' history of nausea and vomiting anuria and constipation. She had been well until January 1947 when a cancer of the uterus was diagnosed and treated with radium. She then developed a vesicovaginal fistula, which had not been closed despite four operations In June 1949 the right ureter was transplanted into the pelvic colon (Coffey s operation) No excretion from the left kidney was found on intravenous urography Diuresis became normal after the operation, but no urine was passed in the natural way The blood urea which had previously been normal, rose immediately after the operation to 192 mg per 100 ml. and later fell to about 100 mg The patient had several bouts of fever which were ascribed to ascending urinary infection and treated with penicillin streptomycin. and sulphamethylthiodiazole After the operation the patient had complained of constant tiredness

First Admission—The patient was very ill cold and cyanotic with uræmic fœtor Her skin and mucosæ were dry and flabby Her temperature was normal, pulse rate 64 per min. and blood pressure 100/65 mm. Hg It was suspected or rather certain—that she had a negative potassium balance even before the potassium analyses were made, because of the type of respirations and the electrocardiogram. Her respirations were slow at first but after elimination of the acidosis they became frequent and irregular without being of the Cheyne-Stokes type they corresponded to the type found in hypokalæmia and described by Bodansky (1949) and others as fish mouth respiration. The electrocardiogram (fig 1) showed changes characteristic of hypokalæmia low or iso-electric T waves depression of P–Q and S–T intervals prolonged Q–T interval and ventricular extrasystoles (compare fig 2, an electrocardiogram taken after her serum potassium had become normal)

Her potassium and bicarbonate serum levels were very low, but sodium chloride and calcium were within normal limits (fig 3) The administration of isotonic solution of sodium bicarbonate and neutral potassium phosphate in the first few days—the potassium solution had originally been prepared for the treatment of diabetic coma and contained 36 m eq of potassium and 120 m.eq of sodium per litre (Kjerulf-Jensen 1949)—restored the serum bicarbonate to normal without having much effect on the potassium level On the other hand, the serum-calcium fell to 1·8 m.eq per litre (3·6 mg per 100 ml), which caused tetany and prevented the blood from coagulating unless calcium chloride was added The serum-phosphorus was twice the normal value These great changes in calcium and phosphorus were attributed to the parenteral administration of too much phosphate Similar changes were subsequently produced experimentally in animals The removal of calcium from the plasma was thought to be due to its deposition in the bones The large amount of isotonic solutions given caused severe over hydration, the hæmatocrit falling from 32 to 23% and generalised œdema and severe lung œdema developing For the hydræmia two transfusions of whole blood and two intravenous infusions of 100 ml. of 50% glucose were given, which led to slight improvement Despite the severe hydration diuresis was still too small to be measured The patient seemed moribund, but in view of the severe hypokalæmia still present a hypertonic solution (10%) of potassium chloride was given by mouth as a last resort 10 ml every quarter of an hour for fourteen doses Within an hour there was profuse diuresis, the œdema vanished, and the patient s general condition improved remarkably A few hours later, however, she had a slight attack of collapse accompanied by tetany which rapidly disappeared after an intravenous injection of calcium gluconate The patient continued to improve under treatment with hypertonic potassium chloride solution and calcium lactate by mouth Her potassium, calcium and phosphorus levels returned to normal, and her blood-urea fell from 317 to 133 mg per 100 ml During this time in hospital her temperature was unstable but after a four-day course of streptomycin it fell to normal and remained so Radiography on the day before her discharge revealed bilateral lung infiltrations resembling old tuberculous lesions there had been no cough or sputum On her discharge at her own request, after twenty two days in hosp tal, she had regained her normal weight of 8 st 4½ lb (53 kg)

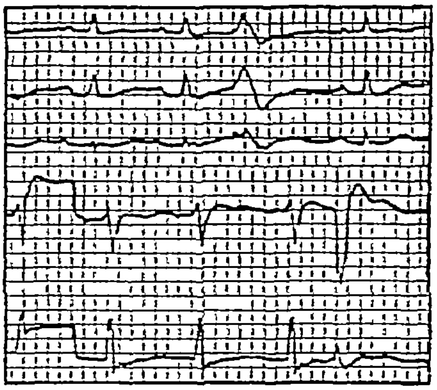

Fig 1—Electrocardiogram in untreated hypokalæmia serum-potassium 1·12 m.eq and serum-calcium 5·1 m.eq per litre P–Q 0·20 sec. Q–R–S 0·03 sec. S–T negative T waves iso-electric or negative ventricular extrasystoles present.

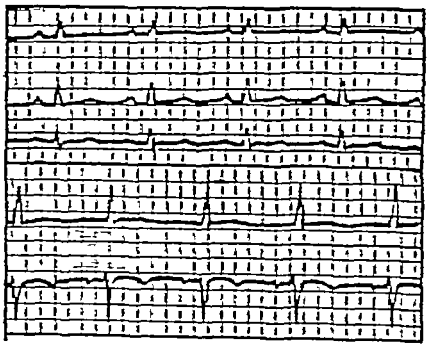

Fig 2—Electrocardiogram after correction of hypokalæmia with potassium salts serum-potassium 4·8 m.eq and serum-calcium 4·1 m.eq per litre R–R 0·7 sec. P–Q 0·18 sec. Q–R–S 0·05 sec. Q–T 0·3 sec. T positive in leads II and III no extrasystoles.

Second Admission—Seventeen days after her discharge she was readmitted for a relapse after two or three days' vomiting and anuria She was not quite so ill as on the first admission and her serum potassium was not quite so low On the other hand, her serum bicarbonate was extremely low (fig 4) No potassium phosphate was given, but a 10% solution of potassium chloride and sodium bicarbonate powder were given by mouth In two days her serum bicarbonate became normal and her serum potassium rose slowly There was a considerable retention of fluid (hæmatocrit fell from 30 to 21%) and her serum phosphorus fell almost to zero, but her serum calcium remained normal and there were no clinical manifestations of calcium deficiency Continued administration of potassium chloride, in smaller daily doses, led to a sudden rise in the serum potassium on the fourth day (by which time 1072 m eq of potassium had been given) to well over normal values The potassium curve indicates that in the first few days of treatment the cells had assimilated a considerable amount of potassium (diuresis had not yet begun) and that the serum potassium did not rise until the supply of potassium exceeded this cellular assimilation From this time her serum phosphorus began to rise without any form of extra phosphate administration Her blood urea varied from 71 to 112 mg per 100 ml Her red cell potassium level was estimated every day in the hope of obtaining some idea of the intracellular potassium deficit The results (fig 5) show that throughout her stay the potassium content of her red cells was below normal, even during intensive administration of potassium when her serum potassium was higher than normal, this finding is in accordance with the conception that the exchange of potassium is slower in the red cells than in most other cells

It was soon possible to re establish her electrolyte balance but this time the anticipated improvement in her general condition did not follow, and the patient gradually developed a continuous high fever and began to cough up sputum containing numerous tubercle bacilli, X ray examination now showed rapid progression of the lung infiltration with cavity formation Her condition was hopeless, and despite penicillin and streptomycin she died 11 days after the start of the pyrexia

Necropsy Findings—Recent tuberculous pneumonia and cavities were found in the left lung and older proliferative tuberculous processes in the right lung There was a bilateral hydronephrosis, the left kidney tissue being only 3–4 mm thick The left ureter was dilated and ended blindly in fibrous scar tissue in the lesser pelvis, the right ureter, which had been implanted in the colon was dilated to the thickness of a finger Microscopy of the kidney tissue revealed no tuberculosis The suprarenal glands were normal There was no sign of recurrence in the uterine cancer, and no internal metastases were found A fat free piece of iliopsoas muscle tissue was analysed, with the following results

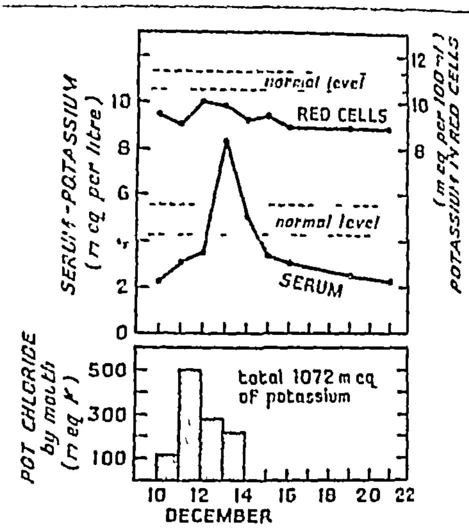

Fig 5—Potassium levels in serum and in red cells and treatment with potassium salts during second stay in hospital

Content	Findings in iliopsoas	Normal range (Mudge and Vislocky 1949)
Total solids (%)	22 6	19 8–21·6
Potassium (m eq per kg)	51	81 0–88·0
Sodium (m eq per kg)	107	30 0–44 9

☐ SOD BICARBONATE
☒ NORMAL LEVELS

Fig 3—Electrolytes in patient's blood and treatment with electrolytes during first stay in hospital

Fig 4—Electrolytes in patient's blood and treatment with electrolytes during second stay in hospital

It will be seen that the potassium content of the muscle was low whereas the sodium was significantly above normal This fits in with the well known view that during potassium deficiency sodium may act as a substitute for potassium in the cells

EXPERIMENTS ON ANIMALS

Experiments were performed in an attempt to reproduce in animals some of the changes observed in the patient's electrolyte balance during treatment

The effect of giving neutral sodium phosphate solution was studied in two normal rabbits weighing 3 kg Phosphate corresponding to 0 4 g of phosphorus was given, first (fig 6) through an œsophageal tube, and secondly (fig 7) by continuous intravenous infusion for 50 minutes In both experiments the serum phosphorus rose while the serum calcium fell from the normal of about 6 m eq to 3 6 and 2 2 m eq per litre, whereas the levels of glucose and potassium were unaffected

Continuous intravenous infusion of 3 m eq of potassium per kg of body weight into a normal rabbit for 40 minutes did not demonstrably affect the serum phosphorus level (fig 8)

DISCUSSION

There were probably several causes for the patient's severe potassium deficiency The supply of potassium was low because of reduced food intake The vomit contained 13 m eq of potassium per litre (50 mg per 100 ml) The renal potassium loss was not measurable, because implantation of the ureter in the intestine made it impossible to collect urine free from fæces, but since it was certain that the patient lost potassium even when she was not vomiting, and when her food intake was normal, it must be assumed that the renal loss was the most important factor in her deficiency Ferris and Odel (1950) found that 79% of 141 patients with bilateral ureterosigmoidostomy showed a tendency to acidosis and hyperchloræmia, with symptoms corresponding to those of our patient, but they do not mention potassium depletion in their patients In their opinion acidosis is caused by reabsorption of chloride through the intestinal mucosa Protracted acidosis is known to be accompanied by a loss of calcium, potassium, and phosphorus from the tissues, and that the rapid correction of acidosis may be accompanied by extremely low extracellular concentrations of these electrolytes and severe clinical symptoms (Rapoport et al 1947)

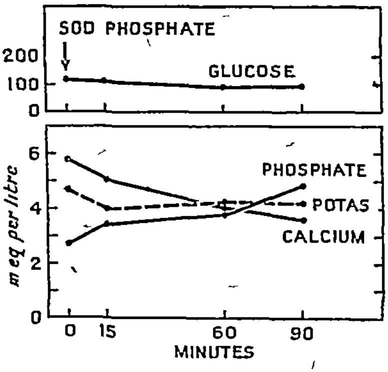

Fig 6—Calcium potassium phosphate and glucose levels in serum of normal rabbit dosed with neutral sodium phosphate solution by mouth.

The total potassium deficit seems to have been considerable in the present case Most of the potassium (1072 m eq) administered in four days must be regarded as having been retained, because in the first three days of this treatment the patient neither vomited nor excreted urine or fæces Her lowest serum potassium level was 1 12 m eq per litre (4 4 mg per 100 ml)

During the first three days of the first stay in hospital (fig 3), potassium was administered in the form of neutral potassium phosphate solution The result was hyperphosphatæmia and hypocalcæmia During the second stay in hospital potassium was administered without previous or simultaneous administration of phosphate The result was hypophosphatæmia Though the hypophosphatæmia produced no clinical symptoms, it must be desirable, in order to encourage assimilation of potassium by the cells, to supply an optimal quantity of phosphate relating to the amount of potassium given The relation between the amounts of potassium and of phosphate (in equivalents) required by the organism is not 1 : 1 The optimal ratio between the ions is about 3 eq of potassium to 1 eq of phosphate to 2 eq of chloride or bicarbonate in the present case, according to our calculations Butler et al (1946) and Reyersbach et al (1948) have used a solution containing 5 eq of potassium to 1 eq of phosphate The optimal relation is, however, subject to individual variation The fact that in the experiment on the rabbit (fig 8) no fall in plasma phosphorus level was demonstrable during infusion with potassium chloride is in accordance with the assumption that the disappearance of phosphate from the plasma was connected with the assimilation of potassium and phosphorus by the cells An increase in the extracellular potassium level alone does not affect the plasma phosphorus level.

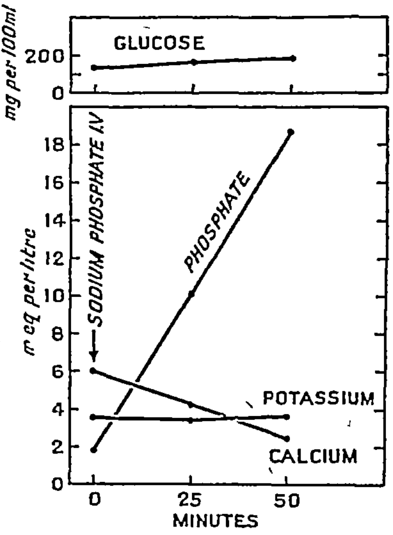

Fig 7—Calcium potassium phosphate and glucose levels in serum of normal rabbit infused intravenously with neutral sodium phosphate solution continuously for 50 min at a rate of 0·49 m eq of phosphorous an hour

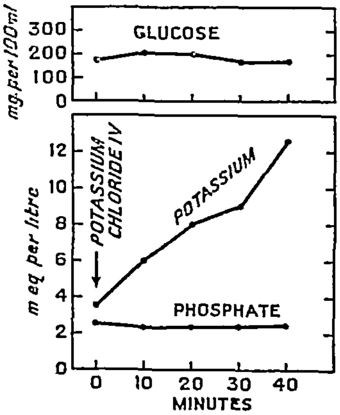

Fig 8—Potassium, phosphate, and glucose levels in serum of normal rabbit infused intravenously with potassium chloride solution continuously for 40 min to a total of 9 m.eq of potassium

CONCLUSIONS

Severe intracellular potassium deficiency should be treated with concentrated solution of potassium salts, even in the presence of severe dehydration These solutions should be given by mouth only

The initial dose of potassium salts should be accompanied by phosphate The optimal ratio (in equivalents) suggested is 3 of potassium to 1 of phosphate The remaining 2 equivalents of anion may be given as chloride or bicarbonate. Too much phosphate tends to produce hypocalcæmia, with the risk of tetany

During intensive treatment with potassium there is always a risk of acute hyperkalæmia, which develops when the amount of potassium given exceeds the amount which the cells can assimilate This risk can be reduced by giving potassium salts by mouth and by making frequent estimations of the plasma potassium level

SUMMARY

Acute hypokalæmia (plasma potassium level 1 12 m eq per litre) developed in a woman of 44 with chronic kidney disease It was combated successfully with parenteral and oral potassium salts In four days the patient retained 1072 m eq of potassium and was dramatically relieved

The administration of neutral potassium phosphate caused hyperphosphatæmia and hypocalcæmia, with temporary tetany and inhibition of blood clotting

The administration of a concentrated solution of potassium chloride without a simultaneous supply of phosphate reduced the serum phosphate to zero There were no demonstrable changes in serum calcium or any clinical symptoms

In experiments on normal rabbits the administration of sodium phosphate lowered the serum calcium while the serum potassium remained constant The infusion of potassium chloride solution in normal rabbits did not lower the serum phosphate These findings agree with the conception that the fall in serum phosphate is intimately connected with the assimilation of potassium by the potassium deficient cells

UNIVERSITY OF MANCHESTER

METALLIC mercury and mercurial salts are handled and used in various industries, and as a result considerable attention has been paid to the risk of chronic mercurial poisoning A comparatively recent development is the use of grey powder (hydrargyrum cum creta) in the investigation of fingerprints

The chief drawbacks which have confronted investigators of industrial mercury poisoning have been (1) the difficulty of accurately determining minute amounts of mercury, (2) the fact that the three main manifestations of chronic mercurial poisoning—erethism, tremor, and stomatitis—are, particularly in mild cases, difficult to distinguish from conditions which arise fairly commonly in people who have no contact with mercury in any form, and (3) the apparently considerable quantitative differences in the reaction of different people to mercury, since it has generally been impossible to trace any correlation between the presence or severity of the symptoms and the probable amounts of mercury absorbed

The difficulty of accurately determining minute quantities of mercury may now be regarded as having been overcome, since Milton and Hoskins (1947) have published a method by which it is possible to determine mercury in urine in concentrations as low as 0 005 part per million The other difficulties still remain.

PREVIOUS INVESTIGATIONS

A comprehensive survey of the historical aspect of chronic mercury poisoning in industry was made by Buckell et al (1946) They also investigated workers in a thermometer factory, and the amount of mercury excreted in the urine in twenty four hours ranged from 136 to 3478 μg The three characteristic symptoms (erethism, tremor, and stomatitis) were looked for and their presence or absence was apparently independent of the urinary mercury level The average mercury level was about the same in the symptomless workers as in those found to have any or all of these three

One employee had at work an excretion of 2300 mg After seventeen days' absence he had an excretion of 1290 mg indicating that mercury was probably still being absorbed from the clothing Estimation of the mercury content of the air showed that the rate of excretion was very much more than could be absorbed by respiration Washings from the hands contained up to 9800 μg per worker It was concluded that absorption took place largely through the skin or the alimentary tract In one case the daily excretion of mercury during two separate weeks ranged from 96 to 1000 μg In a further week in the same case the range was 66–270 μg In 14 controls free from any contact with mercury the highest excretion of mercury was 90 μg and the lowest 5 μg, the average being 31 5 μg

Agate and Buckell (1949) examined 32 police officers who used grey powder in the demonstration of fingerprints In their series only two symptoms were manifest —tremor and erethism—and 4 of the 32 police officers showed both symptoms Again there seemed to be no relationship between the symptoms and the amounts excreted The average excretion was higher in the officers without symptoms than in those with one or both symptoms

At first sight these two investigations seem to indicate that there is no relationship between the presence or severity of the symptoms and the amount of mercury ingested or excreted There are, however, several factors to consider before such a conclusion is drawn

The chief difficulties in interpreting the figures seem to be

(1) Except in 2 cases in the thermometer factory, the amount of mercury excreted by each person was estimated during one day only,

(2) The symptoms are not easily diagnosed and assessed, particularly in mild cases

The second difficulty may not have been of much significance because the observers were skilled and were well aware of the pitfalls, but an indication of what is considered an excessive or toxic dose, apart from idiosyncrasy, would help in other cases It is clear from the published findings in the above investigations that the first difficulty cannot be neglected We have found that the amount of mercury excreted varies considerably from day to day, and this is illustrated in the one case reported by Buckell et al (1946) in which repeated daily determinations were made In one week the daily variation was from 96 to 1000 μg, and in another week from 66 to 270 μg It is evident that care must be exercised in drawing deductions from the excretion on a single day This must be remembered when interpreting the results of Agate and Buckell (1949), since they also determined the excretion on one day only for each police officer

PRESENT INVESTIGATION

We felt that further information was advisable before condemning the use of mercury with chalk (*B.P*) in the detection of fingerprints, particularly since, in spite of the practice being world wide, no severe case of mercurial poisoning from this cause could be traced This work was undertaken to find out whether any effect could be detected clinically in men investigating fingerprints with the mercury powder The best indication of the probable amount of mercury ingested seemed to be the amount excreted in the urine Buckell et al (1946) and other workers have concluded that the bulk of the mercury is probably absorbed through the skin or finds its way into the body by the mouth The mouth is probably the main source of the intake, and one may assume that the mercury gets to the mouth mainly from the hands via the food No reliable published figures could be found to correlate the amount excreted in the urine with the quantity ingested, but probably at least a rough relationship exists Even in cases where the excretion and therefore probably the intake are comparatively large the actual amounts are really very small Large variations in the daily intake are therefore to be expected, since 1000 µg of mercury with chalk, containing 330 µg of metallic mercury, is a scarcely visible quantity, and the contamination of the hands and therefore possibly of the food is largely accidental and must be extremely variable Obviously the amounts of mercury ingested and excreted may bear little relationship to the total amount of exposure to the powder, especially when judged by a single test of the excretion Much must depend on the technique of using the powder, cleaning the hands and clothes, &c

Two officers, A with twelve years' and B with nine years' experience in "dusting," volunteered to help in the investigation and agreed to provide material for examination Twenty four hour specimens of urine were taken from both at intervals over a few months to find whether the absorption of mercury, judged by the excretion, could be related to the amount of work done, and whether the amount found could be classed as excessive It was also decided to try simple means to reduce the intake and to determine if the effect of such means would be demonstrable No erethism, stomatitis, or tremor was found in either volunteer This was confirmed by Prof R E Lane, of the department of occupational health in Manchester University, and Dr J F Wilkinson, of the department of hæmatology, Manchester Royal Infirmary, who made independent examinations Specimens of handwriting and free line drawing were without fault The twenty four hour samples were taken during ordinary working periods except where otherwise indicated The process for the determination of the mercury was substantially that given by Milton and Hoskins (1947) The results were as follows

Date	Mercury (µg) excreted in 24 hours		Comments
	Subject A	Subject B	
Nov 8 1949	—	99	
Nov 11 1949	396	182	
Nov 17 1949	394	284	
Nov 25 1949	214	96	
Dec 1, 1949	697	100	Busy week previously
Dec 28 1949	85	53	A, six days' holiday, B four days' holiday
Feb 13, 1950	208	93	Overalls worn, and more careful attention to washing of hands from Feb 7 1950
Feb 22 1950	99	40	
March 14 1950	78	42	

It was thought possible that the higher figures of A were due to the fact that he performs duty in civilian clothes and visits scenes of crime during the day, with probable further absorption from the clothes he continues to wear B, on the other hand, does most of his work in uniform inside police headquarters

DISCUSSION

From Nov 8 to Dec 28, 1949, no special precautions during "dusting" were taken, the methods being those used by these officers for many years previously These figures therefore give a picture of the absorption which had been taking place for years In the case of subject A four samples taken during ordinary working periods gave an average daily excretion of 425 µg , and subject B five samples similarly taken gave 152 µg daily It should be emphasised that, though these figures probably represent fairly closely the average excretion, excluding holiday periods, over many years, there were no clinical signs of mercurial poisoning It is evident that the rate of excretion rapidly follows the rate of intake, since the excretion fell to almost normal proportions after six days' holiday in the case of A and four days' holiday in the case of B

After a week's wearing of overalls during the actual use of the powder and with more careful washing of the hands the findings for each officer were lower than any previously obtained during full working periods In the case of A the figure was less than half of the previous average, and in the case of B it was two thirds The two further samples taken fifteen days and thirty five days after the start of these simple precautions gave very low figures Probably the powder previously deposited on the clothes, &c , had been removed by this date The excretion of A was then about the same as the higher results found by Buckell et al (1946) in normal people who had no known contact with mercury, and in the case of B well below that of many persons with no known contact

Mercury can cause chronic poisoning but, apart from hypersensitivity and/or idiosyncrasy, only when the intake or absorption exceeds a certain, as yet undetermined, amount It is evident from the work of Buckell et al (1946) that mercury in appreciable quantities is excreted by most, if not all, the population, and therefore there must be an intake of mercury, probably in the food The quantitative factor therefore becomes of paramount importance Buckell et al. (1946) found in fourteen normal persons with no known contact with mercury in any form a daily range of excretion from 5 to 90 µg , average 31 5 µg These figures are similar to those observed by us, who obtained a figure of 21 µg for the average daily excretion in one person

Mercury in various forms has been and is often used medicinally, often over very long periods A normal dosage for certain purposes would be about gr 1 (64,800 µg) weekly for twelve weeks, a total of about 800,000 µg Symptoms of mercurial poisoning which then occasionally occur are regarded as indicating hyper sensitivity It is therefore evident that the normal human body detoxicates small quantities of mercury throughout life, and can for fairly long periods deal with comparatively large amounts

We do not wish to belittle the danger of chronic mercurial poisoning in those who regularly handle mercury in any form We feel, however, that valuable information about the probability of such poisoning can be obtained by estimating fairly often the daily excretion of mercury by such people The two police officers who were examined have been responsible for all the fingerprint work in the area, and have used grey powder exclusively for many years They have shown no clinical sign of chronic mercurial poisoning in spite of an average daily excretion of 425 µg and 152 µg Simple precautions reduced this excretion to daily averages of 89 µg and

41 µg, which are within the limits observed in persons without any known contact with mercury We consider it desirable that clinical observations should be made and the urinary excretion of mercury estimated over a considerable period in each of a large number of cases before conclusions are drawn about the possible dangers of chronic mercurial poisoning, particularly in fingerprint detection

SUMMARY

Two police officers heavily engaged for years in fingerprint detection with mercurial powder were examined No clinical signs of mercurial poisoning were detected by several independent observers

The average daily urinary excretion of mercury over a period of two months with no precautions was 425 µg and 152 µg, excluding holiday periods By care in washing the hands and the wearing of overalls these amounts were reduced by three quarters

It is suggested that, before the use of mercurial powder for fingerprint detection is considered as representing a definite risk, fairly protracted observations should be made on each of a large number of people who are prepared to exercise care in taking simple hygienic measures

There is some evidence that the urinary excretion of mercury can be used to supply information about the amount ingested

EFFECT OF VENOUS OCCLUSION ON PERIPHERAL ARTERIAL BLOOD-FLOW

JESSE E THOMPSON* JOHN R VANE†
M D Harvard B Sc Oxfd
From The Nuffield Institute for Medical Research, Oxford

INTERMITTENT venous occlusion, by means of a pneumatic cuff placed round the thigh was introduced in 1936 by Collens and Wilensky for the treatment of patients with obliterative vascular disease The rationale was that the reactive hyperæmia which follows release of the occluding pressure (Lewis and Grant 1925) might promote the development of the collateral circulation Collens and Wilensky used intermittent venous occlusion pressures of 30–90 mm Hg, with a cycle of two minutes on and two minutes off, and they reported beneficial results in a high proportion of their 124 patients

Since its introduction numerous other investigators have examined the therapeutic effects of intermittent venous occlusion in man, yet there does not seem to be any unanimity about its efficacy Whereas Collens and Wilensky (1937), Brown and Arnott (1937, 1938), Evoy and de Takats (1948), and Linton (1949) have found it beneficial in the treatment of vascular disease, Allen et al (1946) and Smithwick (1949) consider it to be of little or no use Among those who use the method and find it helpful some believe it is of value only in acute arterial emergencies, such as embolism and thrombosis, while others use it also in chronic conditions

SUPPOSED EFFECTS

Two types of vascular change have been supposed to result from intermittent venous occlusion (1) the acute effects, which include the changes occurring during the period of occlusion and immediately after its release, and (2) the chronic effects, which may include the changes occurring in the collateral circulation to the limb over a long period

The acute effects have been investigated in man and animals with conflicting results The chronic effects have been observed only in patients with obliterative vascular disease, again with conflicting results, and have not been subjected to direct experiment Direct measurement of changes in the collateral circulation in patients has not yet proved feasible, and in animals such long term investigations are admittedly difficult and have not been undertaken

PREVIOUS INVESTIGATIONS

Methods used for examining acute effects of intermittent venous occlusion on arterial blood flow are of two types (1) the first has been designed to study the circulation in man by various indirect methods when venous occlusion is applied for a limited time, and (2) the second has been designed to study the circulation in laboratory animals by measuring the arterial blood flow directly during and after short periods of venous occlusion

Allen and McKechnie (1937) studied the effect of intermittent venous occlusion on the surface temperature of 19 patients with and without arterial disease, and could find no evidence of significant or consistent vasodilatation resulting from the procedure

Veal and McCord (1939), testing blood-oxygen changes in 11 healthy males after intermittent venous occlusion, concluded there was no increase in the rate or volume of blood flow, and that a true reactive hyperæmia was not produced.

Abramson et al (1941), using a plethysmographic method, found no increase in blood flow either during or after venous occlusion in the leg or forearm, but sometimes observed a slight increase in the hand and foot

Friedland et al (1943) and Halperin et al (1948) using capillary microscopy, skin temperature readings, plethysmography, and venous blood oxygen differences in human patients, concluded that blood flow in the limbs is not increased during venous occlusion but is usually decreased They postulated two causes for this observation (1) a reduction in the pressure gradient from artery to vein, due to increased venous pressure and (2) a decrease in the calibre of small vessels in the compressed area causing an increased resistance to flow

The evidence obtained by indirect methods in man suggests that there is no increase in mean arterial blood flow during venous occlusion

Linton et al (1941) reported changes in arterial flow during venous occlusion in dogs They used a thermostromuhr method Venous occlusion was produced either with a pneumatic cuff placed round the thigh or by clamping the major veins During venous occlusion the arterial inflow to the hind limb increased, and immediately after release of the occlusion the arterial flow decreased The changes were greater when the pneumatic cuff was used than when the major veins were occluded directly On the basis of this rather surprising result Linton et al. recommended that the period of venous obstruction be longer than the period of release when intermittent venous occlusion was to be used for therapy in man. As it did not appear logical that arterial inflow should increase during venous obstruction, Gregg et al (1948) studied the problem again

They used three different types of instruments to measure arterial blood flow in the dog's hind leg (1) a Baldes Herrick thermostromuhr, (2) an orifice meter, and (3) an optically recording rotameter With the thermostromuhr they obtained the same results as Linton—i e, an apparent increase in arterial flow during venous occlusion, and an apparent decrease following its release With the other two methods they consistently found a decrease in arterial flow during venous occlusion and an increase on release

The thermostromuhr is a complicated device which relates the rate of blood flow to changes in the differential temperature between two thermojunctions the flowing blood being heated by a unit situated between the two thermojunctions Tests by Gregg et al (1948) have revealed serious inaccuracies in the Baldes Herrick thermostromuhr method of measuring blood flow since many factors other than blood flow influence the results significantly "The amount of backflow in the flow pattern is particularly important since the flow pattern in most arteries either normally contains backflow or it can be induced and the instrument is so sensitive that such a change can cause the device to indicate incorrectly the directional change in flow."

---

* During the tenure of a Rhodes scholarship and a Fulbright grant
† During the tenure of a grant from the Medical Research Council

Since the rotameter and orifice meter are not subject to the same criticisms as the thermostromuhr, Gregg et al (1948) concluded that the results obtained with the thermostromuhr during venous occlusion were diametrically opposed to the truth. They therefore stated that the arterial blood flow decreases during venous occlusion and increases after release of the occlusion.

PRESENT METHODS

In the present investigation we studied the acute effects of venous occlusion on the rate of arterial flow in animals by two direct methods not previously used for this purpose.

Cats weighing 1·8–3·5 kg were anæsthetised with chloralose 70 mg per kg of body weight or with pentobarbitone 30 mg per kg of body weight. In some experiments the hind legs were denervated either before or during the perfusion. One hind leg was perfused through the iliac artery, the hypogastric and caudal arteries being tied; occasionally, in small cats both hind legs were perfused from the aorta. The rate of blood flow and the perfusion pressure were both measured directly. A carotid and a brachial artery were cannulated, and blood was taken from these into the perfusion pump through a resistance. The blood, kept at 37°C by a hot-water jacket, was pumped into the leg and returned by the normal venous channels. The rate of blood flow was recorded by direct measurement with a volume recorder attached to the pump, and was registered as a series of vertical lines on a smoked drum. At the end of each experiment the recorder was calibrated. Tested with an artificial circulation the greatest error found was + 4% at 45 ml per min (the highest rate of flow obtained in this work). It is important to emphasise that the actual volume of blood entering the leg was measured, so that the errors associated with indirect methods (such as the thermostromuhr) were eliminated. Full details of the perfusion method will be published elsewhere.

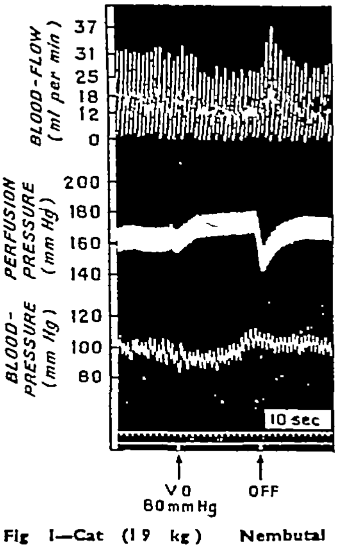

Fig 1—Cat (1·9 kg) Nembutal anæsthesia with bilateral lumbar sympathectomy. Both hind legs perfused from bifurcation of aorta. Blood pressure recorded from left brachial artery. Flow before occlusion was 32 ml per min. At first mark, cuffs round both legs were inflated to 80 mm Hg: the flow was reduced to 26 ml per min. On release of the occlusion the rate of flow rose to a peak of 37 ml per min but rapidly fell again to a level of 28 ml per min. Thus the flow after occlusion was lower than that before.

Serial radiographs were taken at intervals of 0·5–1·5 sec after the injection of 'Thorotrast' (2–3 ml) into the abdominal aorta. The injections were made through a 'Polythene' tube tied into the stump of the inferior mesenteric artery.

Venous occlusion was achieved by wrapping a pneumatic cuff round the thigh and inflating it to known pressures measured with a mercury manometer.

RESULTS

The effect of venous occlusion on the rate of blood-flow in the perfused leg was studied in 12 cats.

When the cuff round the perfused hind limb was inflated to a fixed pressure of 20–80 mm Hg (27 observations), 80–100 mm Hg (11 observations), and 100–200 mm Hg (17 observations) for two or three minutes, the arterial inflow always decreased (figs 1 and 2). In not one of these 55 occlusions was an increased flow recorded during the occlusion. Sometimes, immediately after release of the pressure, reactive hyperæmia was observed, but this never lasted longer than twenty to thirty seconds and in no instance compensated for the reduced flow during occlusion. The reactive hyperæmia, when present, was followed by a reduction in blood flow to the rate before occlusion or, in several experiments, even further (fig 1).

To study further the effects of venous occlusion, individual veins were clamped with 'Bulldog' clips. The arterial inflow decreased in all of the 21 instances where the vena cava, the common iliac, the external iliac (fig 2), or the femoral vein was clamped.

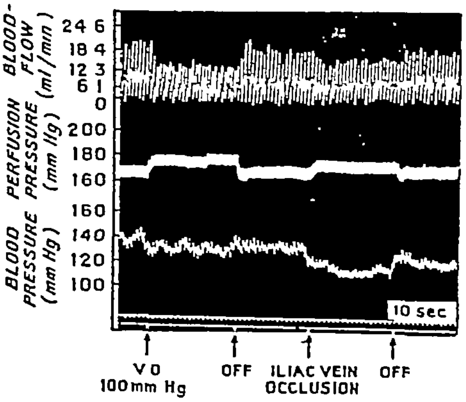

Fig 2—Cat (2·6 kg) chloralose anæsthesia. Right hind leg perfused. Venous-occlusion cuff inflated to 100 mm Hg for 3 min. Blood-flow reduced from 20 ml per min to 13 ml per min. After release rate of flow was 19 ml per min: this was reduced to 15 ml per min by clamping the iliac vein for 3 min. Note fall in blood-pressure characteristic of this type of occlusion indicating pooling of blood in the leg.

Thus it became obvious that, if any over all increase in blood flow was to be obtained during intermittent venous occlusion, it must be through the reactive hyperæmia overcompensating for the reduction in flow during the occlusion. A cycle of occlusion and release was therefore adopted, with the cuff inflated for 30 seconds, and deflated for 30 seconds. Under these conditions an over all increase in flow during intermittent venous occlusion was never observed. Nine experiments made with intermittent venous occlusion pressure of 60–300 mm Hg were made, each run lasting for five to ten minutes. The reactive hyperæmia in no instance compensated for the decreased blood-flow during occlusion; although reduced blood flow was observed on all occlusions, no reactive hyperæmia followed occlusions at the lower pressures (fig 3). The rate of blood flow after intermittent venous occlusion was never greater than the rate before; in some instances it was less. In all these varieties of occlusion removal of the lumbar sympathetic trunks or cutting the sciatic and femoral nerves, or both, did not sensibly alter the results.

To study the circulation visually during venous occlusion, and to confirm the results obtained on the perfused legs, radiographs were taken of both hind legs, one of which was occluded with the cuff for two minutes before the injection of thorotrast. In each of the 5 cats studied the radiographs showed that filling of the vessels below the cuff on the occluded leg was much delayed, compared with the control leg. There was also a considerable decrease in the number of small arterial vessels seen under the occluding cuff. Fig 4 is taken from a typical series and shows both these effects.

DISCUSSION

The hypothesis that intermittent venous occlusion promotes the development of collateral circulation has been based on two alleged effects during and immediately after release of the occlusion:

1. An increase in arterial inflow during venous occlusion (Linton et al 1941).

41 μg, which are within the limits observed in persons without any known contact with mercury. We consider it desirable that clinical observations should be made and the urinary excretion of mercury estimated over a considerable period in each of a large number of cases before conclusions are drawn about the possible dangers of chronic mercurial poisoning, particularly in fingerprint detection.

SUMMARY

Two police officers heavily engaged for years in finger print detection with mercurial powder were examined. No clinical signs of mercurial poisoning were detected by several independent observers.

The average daily urinary excretion of mercury over a period of two months with no precautions was 425 μg and 152 μg, excluding holiday periods. By care in washing the hands and the wearing of overalls these amounts were reduced by three quarters.

It is suggested that, before the use of mercurial powder for fingerprint detection is considered as representing a definite risk, fairly protracted observations should be made on each of a large number of people who are prepared to exercise care in taking simple hygienic measures.

There is some evidence that the urinary excretion of mercury can be used to supply information about the amount ingested.

EFFECT OF VENOUS OCCLUSION ON PERIPHERAL ARTERIAL BLOOD-FLOW

JESSE E THOMPSON* JOHN R VANE†
M D Harvard B Sc Oxfd

From The Nuffield Institute for Medical Research, Oxford

INTERMITTENT venous occlusion, by means of a pneumatic cuff placed round the thigh was introduced in 1936 by Collens and Wilensky for the treatment of patients with obliterative vascular disease. The rationale was that the reactive hyperæmia which follows release of the occluding pressure (Lewis and Grant 1925) might promote the development of the collateral circulation. Collens and Wilensky used intermittent venous occlusion pressures of 30–90 mm Hg, with a cycle of two minutes on and two minutes off, and they reported beneficial results in a high proportion of their 124 patients.

Since its introduction numerous other investigators have examined the therapeutic effects of intermittent venous occlusion in man, yet there does not seem to be any unanimity about its efficacy. Whereas Collens and Wilensky (1937), Brown and Arnott (1937, 1938), Evoy and de Takats (1948), and Linton (1949) have found it beneficial in the treatment of vascular disease, Allen et al (1946) and Smithwick (1949) consider it to be of little or no use. Among those who use the method and find it helpful some believe it is of value only in acute arterial emergencies, such as embolism and thrombosis, while others use it also in chronic conditions.

SUPPOSED EFFECTS

Two types of vascular change have been supposed to result from intermittent venous occlusion: (1) the acute effects, which include the changes occurring during the period of occlusion and immediately after its release; and (2) the chronic effects, which may include the changes occurring in the collateral circulation to the limb over a long period.

The acute effects have been investigated in man and animals with conflicting results. The chronic effects have been observed only in patients with obliterative vascular disease, again with conflicting results, and have not been subjected to direct experiment. Direct measurement of changes in the collateral circulation in patients has not yet proved feasible, and in animals such long term investigations are admittedly difficult and have not been undertaken.

PREVIOUS INVESTIGATIONS

Methods used for examining acute effects of intermittent venous occlusion on arterial blood flow are of two types: (1) the first has been designed to study the circulation in man by various indirect methods when venous occlusion is applied for a limited time, and (2) the second has been designed to study the circulation in laboratory animals by measuring the arterial blood flow directly during and after short periods of venous occlusion.

Allen and McKechnie (1937) studied the effect of intermittent venous occlusion on the surface temperature of 19 patients with and without arterial disease, and could find no evidence of significant or consistent vasodilatation resulting from the procedure.

Veal and McCord (1939), testing blood oxygen changes in 11 healthy males after intermittent venous occlusion, concluded there was no increase in the rate or volume of blood flow, and that a true reactive hyperæmia was not produced.

Abramson et al (1941), using a plethysmographic method, found no increase in blood flow either during or after venous occlusion in the leg or forearm, but sometimes observed a slight increase in the hand and foot.

Friedland et al (1943) and Halperin et al (1948), using capillary microscopy, skin temperature readings, plethysmography, and venous blood oxygen differences in human patients, concluded that blood flow in the limbs is not increased during venous occlusion but is usually decreased. They postulated two causes for this observation: (1) a reduction in the pressure gradient from artery to vein due to increased venous pressure; and (2) a decrease in the calibre of small vessels in the compressed area causing an increased resistance to flow.

The evidence obtained by indirect methods in man suggests that there is no increase in mean arterial blood flow during venous occlusion.

Linton et al (1941) reported changes in arterial flow during venous occlusion in dogs. They used a thermostromuhr method. Venous occlusion was produced either with a pneumatic cuff placed round the thigh or by clamping the major veins. During venous occlusion the arterial inflow to the hind limb increased, and immediately after release of the occlusion the arterial flow decreased. The changes were greater when the pneumatic cuff was used than when the major veins were occluded directly. On the basis of this rather surprising result Linton et al. recommended that the period of venous obstruction be longer than the period of release when intermittent venous occlusion was to be used for therapy in man. As it did not appear logical that arterial inflow should increase during venous obstruction, Gregg et al (1948) studied the problem again.

They used three different types of instruments to measure arterial blood flow in the dog's hind leg: (1) a Baldes Herrick thermostromuhr; (2) an orifice meter; and (3) an optically recording rotameter. With the thermostromuhr they obtained the same results as Linton—i e, an apparent increase in arterial flow during venous occlusion, and an apparent decrease following its release. With the other two methods they consistently found a decrease in arterial flow during venous occlusion and an increase on release.

The thermostromuhr is a complicated device which relates the rate of blood flow to changes in the differential temperature between two thermojunctions, the flowing blood being heated by a unit situated between the two thermojunctions. Tests by Gregg et al (1948) have revealed serious inaccuracies in the Baldes Herrick thermostromuhr method of measuring blood flow since many factors other than blood flow influence the results significantly. 'The amount of backflow in the flow pattern is particularly important since the flow pattern in most arteries either normally contains backflow or it can be induced, and the instrument is so sensitive that such a change can cause the device to indicate incorrectly the directional change in flow '

Since the rotameter and orifice meter are not subject to the same criticisms as the thermostromuhr, Gregg et al (1948) concluded that the results obtained with the thermostromuhr during venous occlusion were diametrically opposed to the truth They therefore stated that the arterial blood flow decreases during venous occlusion and increases after release of the occlusion

PRESENT METHODS

In the present investigation we studied the acute effects of venous occlusion on the rate of arterial flow in animals by two direct methods not previously used for this purpose

Cats weighing 1 8–3 5 kg were anæsthetised with chloralose 70 mg per kg of body weight or with pentobarbitone 30 mg per kg of body weight In some experiments the hind legs were denervated either before or during the perfusion. One hind leg was perfused through the iliac artery, the hypogastric and caudal arteries being tied, occasionally, in small cats both hind legs were perfused from the aorta. The rate of blood flow and the perfusion pressure were both measured directly A carotid and a brachial artery were cannulated, and blood was taken from these into the perfusion pump through a resistance The blood, kept at 37°C by a hot water jacket, was pumped into the leg and returned by the normal venous channels The rate of blood flow was recorded by direct measurement with a volume recorder attached to the pump and was registered as a series of vertical lines on a smoked drum At the end of each experiment the recorder was calibrated Tested with an artificial circulation, the greatest error found was – 4% at 45 ml per min. (the highest rate of flow obtained in this work) It is important to emphasise that the actual volume of blood entering the leg was measured so that the errors associated with indirect methods (such as the thermostromuhr) were eliminated Full details of the perfusion method will be published elsewhere

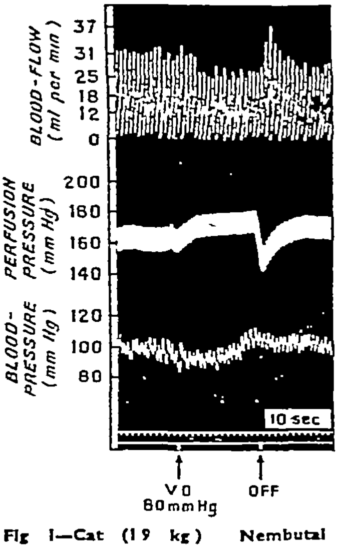

Fig 1—Cat (1 9 kg) Nembutal anæsthesia with bilateral lumbar sympathectomy Both hind legs perfused from bifurcation of aorta. Blood pressure recorded from left brachial artery Flow before occlusion was 32 ml per min. At first mark cuffs round both legs were inflated to 80 mm Hg the flow was reduced to 26 ml per min On release of the occlusion the rate of flow rose to a peak of 37 ml per min but rapidly fell again to a level of 28 ml per min Thus the flow after occlusion was lower than that before.

Serial radiographs were taken at intervals of 0·5–1 5 sec after the injection of 'Thorotrast' (2–3 ml.) into the abdominal aorta The injections were made through a 'Polythene tube tied into the stump of the inferior mesenteric artery

Venous occlusion was achieved by wrapping a pneumatic cuff round the thigh and inflating it to known pressures measured with a mercury manometer

RESULTS

The effect of venous occlusion on the rate of blood-flow in the perfused leg was studied in 12 cats

When the cuff round the perfused hind limb was inflated to a fixed pressure of 20–80 mm Hg (27 observations), 80–100 mm Hg (11 observations), and 100–200 mm Hg (17 observations) for two or three minutes, the arterial inflow always decreased (figs 1 and 2) In not one of these 55 occlusions was an increased flow recorded during the occlusion Sometimes, immediately after release of the pressure, reactive hyperæmia was observed, but this never lasted longer than twenty to thirty seconds and in no instance compensated for the reduced flow during occlusion The reactive hyperæmia when present, was followed by a reduction in blood flow to the rate before occlusion or, in several experiments, even further (fig 1)

To study further the effects of venous occlusion, individual veins were clamped with 'Bulldog' clips The arterial inflow decreased in all of the 21 instances where the vena cava, the common iliac, the external iliac (fig 2), or the femoral vein was clamped

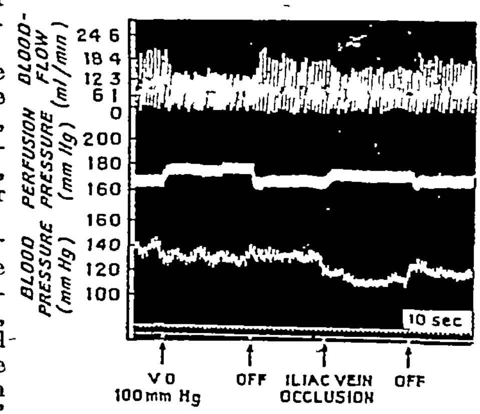

Fig 2—Cat (2 6 kg) chloralose anæsthesia. Right hind leg perfused. Venous-occlusion cuff inflated to 100 mm Hg for 3 min Blood flow reduced from 20 ml per min to 13 ml per min. After release rate of flow was 19 ml per min this was reduced to 15 ml per min by clamping the iliac vein for 3 min Note fall in blood pressure characteristic of this type of occlusion indicating pooling of blood in the leg

Thus it became obvious that, if any over-all increase in blood flow was to be obtained during intermittent venous occlusion, it must be through the reactive hyperæmia overcompensating for the reduction in flow during the occlusion A cycle of occlusion and release was therefore adopted, with the cuff inflated for 30 seconds, and deflated for 30 seconds Under these conditions an over-all increase in flow during intermittent venous occlusion was never observed Nine experiments made with intermittent venous occlusion pressure of 60–300 mm Hg were made, each run lasting for five to ten minutes The reactive hyperæmia in no instance compensated for the decreased blood flow during occlusion, although reduced blood flow was observed on all occlusions, no reactive hyperæmia followed occlusions at the lower pressures (fig 3) The rate of blood-flow after intermittent venous occlusion was never greater than the rate before, in some instances it was less. In all these varieties of occlusion removal of the lumbar sympathetic trunks or cutting the sciatic and femoral nerves, or both, did not sensibly alter the results

To study the circulation visually during venous occlusion, and to confirm the results obtained on the perfused legs, radiographs were taken of both hind legs, one of which was occluded with the cuff for two minutes before the injection of thorotrast In each of the 5 cats studied the radiographs showed that filling of the vessels below the cuff on the occluded leg was much delayed, compared with the control leg There was also a considerable decrease in the number of small arterial vessels seen under the occluding cuff Fig 4 is taken from a typical series and shows both these effects

DISCUSSION

The hypothesis that intermittent venous occlusion promotes the development of collateral circulation has been based on two alleged effects during and immediately after release of the occlusion

1 An increase in arterial inflow during venous occlusion (Linton et al 1941)

2 A reactive hyperæmia following release of the occlusion, a concept based on the work of Lewis and Grant (1925) and put forward by Collens and Wilensky (1936)

The final proof of reactive hyperæmia rests on the demonstration of increased circulation to an extremity after prolonged intermittent venous occlusion over weeks The clinical evidence on this point is conflicting, the necessary experimental data are lacking altogether

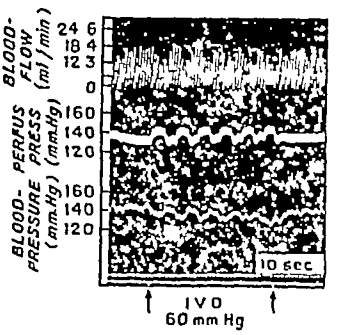

Fig 3—Cat (2 6 kg), chloralose anæsthesia. Right hind leg perfused Blood pressure recorded from left brachial artery Intermittent venous occlusion at 60 mm Hg was applied for 6 min in a cycle of 30 sec. occlusion and 30 sec. release Before occlusion, rate of flow was 18 ml per min Over the period of intermittent venous occlusion the average rate of flow was 14 5 ml per min and after release 16 ml per min

As regards the increase in arterial inflow during venous occlusion, it is clear from the data presented here and by Gregg et al (1948) that arterial inflow considerably *decreases* during venous occlusion It is unfortunate that the vagaries of the Baldes Herrick thermostromuhr should have led to an enthusiastic acceptance of a false rationale by many clinicians It seems logical that venous occlusion by a cuff should lead to a decrease in arterial flow (1) as was pointed out by Halperin et al (1948) the pressure gradient decreases from the arterial to the venous side because of the increased venous pressure, and (2) the calibre of the vessels under the cuff decreases with an accompanying retardation of flow This is demonstrated directly in our radiographs The pressure drop across arterioles is usually about 40 mm Hg, hence at their peripheral end the mean pressure is only some 30 mm Hg It is clear, therefore, that even very low occlusion pressures, far below the diastolic level, will obliterate small arterioles under the cuff, though leaving the main arteries comparatively unaffected

Fig 4—Cat (2 6 kg), nembutal anæsthesia. Blood pressure 120 mm Hg recorded from right carotid artery Cuff round left leg inflated to 80 mm Hg for 2 min before injection of thorotrast. The fourth exposure is shown, taken at 3 2 sec. after the injection Note filling of main arteries in right leg down to ankle but only just past knee in occluded leg Arteries of the smallest visible size in the control limb are not visible under the cuff on the occluded side Note also the compression of soft tissues and displacement of medium sized arteries under the cuff (Left leg is on right of figure)

It is even possible that the presence of the inflated cuff may induce active constriction in the vessels of the occluded leg Slight evidence in favour of this is the fact that in some of our experiments the blood flow following release of the occlusion was lower than the flow preceding occlusion The presence or absence of nerve supply had no effect on this phenomenon

It is well known that the higher the level of the occluding pressure, the greater will be the reactive hyperæmia following release In our experiments the compensatory hyperæmia never approached the amount of blood prevented from entering the limb during the period of occlusion In fact, at the lower occlusion pressures—i e, 60 mm Hg (fig 2)—no significant compensatory rise in flow was observed to follow release of the pressure Further, even when a compensatory hyperæmia did occur it lasted only twenty to thirty seconds, and the subsequent rate of flow was either the same as the pre occlusion rate or lower, it was never higher It thus appears that there is no direct experimental evidence, in man or in animals, in favour of using venous occlusion to increase the arterial blood flow to an extremity Further, the results obtained in acute experiments by both direct and indirect measurements of blood flow point to a decrease in supply of blood to the extremity during the occlusion and no persistent increase after its release Whether repeated venous occlusion increases collateral circulation over a long period has not been proved, no alternate case reports have been published The long term effect of intermittent venous occlusion will not be known until such data are available

SUMMARY

The acute effects of venous occlusion on the rate of arterial inflow to the hind limbs of cats have been studied directly by perfusion and by serial radiography

During venous occlusion the arterial inflow to the extremity decreases

After release of the occlusion, there is commonly a transient increase in arterial flow above the pre occlusion level, but this reactive hyperæmia does not compensate for the decreased flow during occlusion The rate of flow following release is equal to, or less than, the rate preceding occlusion—never higher

Serial radiography showed a delay in the filling of the vessels on the occluded side, and a considerable reduction in the number of visible small arterial vessels under the inflated cuff

There is no direct experimental evidence in man or in animals to substantiate the view that venous occlusion increases the arterial blood flow to an extremity

We wish to thank Dr G S Dawes for guidance in this work, Dr G M Ardran for help in interpreting the radiographs, and Mr N C Shirley and Mr H Elvidge for technical assistance

RECURRENT KAPOSI'S VARICELLIFORM ERUPTION

IN AN ADULT

DIRECTOR WALTER AND ELIZA HALL INSTITUTE OF MEDICAL RESEARCH, MELBOURNE

Kaposi (1887) originally described the vesicular eruption that now bears his name as a complication of eczema in infants and young children. The cases published in the last sixty years indicate that the condition is most common in early childhood but that adults are sometimes affected. Thus Ruchman et al. (1947) found that 75 of the 96 cases previously recorded (i e , 79%) were in children, a quarter of whom were under a year old, the remainder being in adults

Two distinct ætiological types are now recognised the herpetic, due to the virus of herpes simplex, which is the commoner type , and the vaccinial (eczema vaccinatum), due to vaccinia virus

Most of the herpetic cases whether in infants or adults occur as a manifestation of primary herpetic infection—a systemic illness, often severe which is accompanied by the first appearance of specific herpetic antibodies in the blood-stream Thereafter the virus remains latent in the body, producing from time to time, in response to some stimulus, a local infection, such as labial herpes Recurrent herpes rarely if ever becomes generalised, and second attacks of Kaposi's varicelliform eruption are rare (Scott et al 1949) Ruchman et al (1947) reported a case in a patient aged 25, in whom neutralising antibodies were present in the acute stage of the disease but who developed a second attack six weeks after the onset of the first

In the case reported here, attacks of a vesicular eruption recurred for some years, and the diagnosis of recurrent Kaposi's varicelliform eruption of herpetic type was confirmed by clinical and laboratory findings

CASE RECORD

A man aged 36 was admitted to hospital with diabetic acidosis bilateral basal pneumonia and a herpetiform eruption of 3 days duration. For 25 years he had been known to have diabetes mellitus and about twice a year there had been recurrences of labial and facial eruptions consisting of a group of vesicles usually localised to the lips but often involving the cheeks ears and eyebrows The lesions reappeared intermittently at the same site though not as a rule in consecutive attacks The patient s mother and daughter gave a history of labial herpes extending over many years

There seemed to be a relation between the severity of the eliciting stimulus and the extent of the subsequent facial eruptions After a mild common cold with no pyrexia herpes did not usually develop A more severe stimulus such as a febrile illness was followed by localised herpes with one or more groups of discrete lesions A severe systemic illness such as pneumonia was followed by a generalised cutaneous eruption of the type now under discussion

Nineteen years earlier, after the onset of the facial herpes the patient had developed generalised atopic eczema which persisted despite intermittent treatment Twice in the last three years he had been admitted to the Royal Melbourne Hospital with a facial eruption similar to that now described In December 1946, the condition was called infected impetigo ' and in November, 1948 pustular dermatitis,' but on both occasions it was essentially the same as the present illness Each attack had been associated with pneumonia and diabetic imbalance In the present illness he developed a corneal ulcer on the left eye and in the previous year there had been one on the right eye , each ulcer appeared three days after the facial eruption

The present illness commenced with chest pain, pyrexia, cough, and bloodstained sputum On the second day vesicular lesions appeared on the face These began as itchy papules on the nasolabial folds, and in a further 24 hours similar vesicles appeared on the cheeks, eyelids ears, forehead neck and upper part of the chest

On examination the patient had atopic eczema involving his face chest and arms Superimposed was an irregular eruption strictly localised to the eczematous area and consisting of multiple, discrete, and in places confluent lesions with areas of unaffected skin in between The single lesions were circular, averaging 3 mm. in diameter most of them were flat, glistening, yellow and easily broken, yielding purulent fluid some were umbilicated with a surrounding erythema, and contained clear serous fluid , others had red bleeding bases. The whole condition was irritating but not painful. In this attack, according to the patient, lesions appeared for the first time on the forehead. In addition there was inflammation of the pharynx and tonsils but the mucosa of the mouth was free from ulceration. The eyelids were œdematous and ulcerated, and there was a shallow ulcer on the lower and outer quadrant of the left cornea The urine contained glucose and acetone

Diagnosis—On the history and clinical examination a diagnosis of recurrent facial herpes was made together with diabetic acidosis and resolving basal pneumonia

In the past 3 years when intensive but unsuccessful efforts had been made to control the atopic eczema and the diabetes had been unstable it was noted that acidosis was not followed by herpes unless there was an accompanying cold or febrile illness but it invariably led to a rapid and severe flaring up of the eczema Thus a worsening of the eczema associated with an intense stimulus such as pneumonia was followed by a generalised cutaneous eruption

LABORATORY INVESTIGATIONS

Bacteriology—A stained film from the vesicular exudate showed numerous gram positive cocci in clusters , culture produced a coagulase positive penicillin sensitive *Staph aureus*

Isolation and Identification of Virus—The chorio-allantoic membranes of 12-day-old chick embryos inoculated with fluid taken from vesicles on the face and chest developed lesions closely resembling those of the virus of herpes simplex after 48 hours incubation the lesions produced by vesicle fluid from the face and from the chest appeared to be identical. The infective agent was identified by the neutralisation test (Burnet and Lush 1939) and by a direct complement-fixation test using the membranes as antigen and a positive herpes serum (Dudgeon 1950) The membranes showing confluent lesions were ground into a 20% suspension in calcium magnesium saline (pH 7 4) and centrifuged at 2500 r p.m. for 15 minutes The supernatant fluid was used as the antigen in complement-fixation and neutralisation tests This suspension fixed complement at a titre of 1 in 16 in the presence of the positive herpes antiserum no fixation occurred with a normal uninoculated chorio allantoic membrane of the same age The neutralisation test showed that the chorio-allantoic lesions were inhibited to the same extent by the control herpes serum as by the patient s own serum (3rd day), thus establishing herpes simplex virus as the causal agent

Serological Tests—Sera collected from the patient on the 3rd and 21st days of his illness were tested for complement-fixing and neutralising antibodies Complement fixing antibodies were present to a titre of 1 in 16 in the acute phase (3rd day) and 1 in 16 in the convalescent phase (21st day) Neutralising antibodies were present in both specimens

Other Investigations—On the 3rd day of his illness the patient s white-cell count was 8000 per c.mm with 70% polymorphs and his fasting blood sugar level was 370 mg per 100 ml On the 10th day there were 6000 white cells per c.mm. and the fasting blood-sugar was 170 mg per 100 ml

TREATMENT AND PROGRESS

Treatment with 'Sulphamerazine' and penicillin led to rapid resolution of the pneumonia A mild acidosis, as shown by acetone and sugar in the urine, was corrected by adjusting the diet and insulin dosage 'Benadryl' 50 mg three times a day was given on empirical grounds, and local treatment with starch poultices quickly cleared the facial lesions, which by the 12th day had almost completely healed

DISCUSSION

Isolation of the herpes simplex virus from this man's facial and neck lesions, and the demonstration of antibody in his serum in the acute stage (3rd day) as well as in convalescence, established the diagnosis of a recurrent herpetic process The extensive distribution of the lesions and their association with eczematous areas makes it legitimate to describe the condition as recurrent Kaposi's varicelliform eruption

The identification of herpes virus by Seidenberg (1941) and Esser (1941) as a common causal agent in the typical infantile form of Kaposi's syndrome has since been confirmed by many workers in different parts of the world In early childhood the eruption is essentially a manifestation of primary infection with herpes virus, but the numerous reports of Kaposi's syndrome in adults (Barton and Brunsting 1944, Lynch et al 1945, Ruchman and Dodd 1948) show that, if primary infection is delayed, infection of eczematous areas can occur later in life Not all of these adult cases were investigated in detail, but Ruchman and Dodd showed by serological tests that in 8 out of their 9 cases (4 infants and 5 adults) the infection was accompanied by a rise in antibody, thus identifying them as primary infections

The two characteristic features of primary herpes, which normally takes the form of gingivo stomatitis, are (1) the initiation of an infection which will probably persist, mainly in latent form, throughout life, and (2) the first appearance of circulating antibody, which will also remain in the blood for life Infected people are liable to recurrent attacks of herpes which vary in degree, frequency, and relation to the stimulus required to produce them The commonest site for recurrent herpes is the lips or nasolabial folds It is reasonable to suppose that these areas of skin are involved secondarily by extension from the original stomatitis, though this has not been clearly demonstrated Recurrent herpetic lesions rarely involve the mucosa of the mouth The recurrent stomatitis seen in many adults and often attributed to herpes simplex almost certainly has a different ætiology Dodd and Ruchman (1950) report laboratory investigations of several cases of recurrent aphthous or ulcerative stomatitis in adults, but no direct evidence of association with herpes simplex virus was obtained

It is difficult to determine the frequency of recurrent attacks of Kaposi's eruption The published reports suggest that recurrence is rare, though a few cases have been recorded by Scott et al (1949) Of about 10 children with this disease seen at the Hospital for Sick Children in the last few years, none has returned with a recurrence of the eruption, nor with any form of recurrent herpes, although many of them have continued to attend the hospital for treatment of the eczema (Brain 1950, *personal communication*)

In the present case the history indicates that ordinary labial herpes was observed before the onset of eczema It is therefore likely that the primary infection with the virus occurred in early childhood and that, with the development of eczema, affected regions of the skin were infected by transfer of virus from the labial lesions It is impossible to be certain from the patient's history when this transfer took place, but it seems necessary to assume that in the major episodes recurrence in a previously affected region occurred as well as transfer to new vulnerable areas

Cases of this type provide special opportunities not yet explored for the study of a unique and interesting problem in the general pathology of virus infection—the nature of the latent infection and its relation to circulating antibody Burnet's (1945) interpretation of the labial localisation normally seen is that the area involved is infected at the time of the primary stomatitis, that virus continues to exist "symbiotically" in the basal epidermal cells, and that only in such areas can recurrent herpetic lesions appear There are, however, no records of persons having been followed from the time of infantile infection to adult life to establish whether the primary skin involvement occurs in the same site as the subsequent recurrent lesions Cases such as the present one could provide evidence of the extent to which secondarily infected eczematous areas are subject to recurrence. Both aspects should be studied

Epidemiological evidence suggests that, after a primary stomatitis, a child is immune against any further attack of this type, and that maternal antibody can protect most infants up to the age of 12 months (Anderson and Hamilton 1949) It is known, however that a herpetic person can be infected with his own virus by scarification on the skin of the arm, so that circulating antibody is not a complete protection against extrinsic reinfection An eczematous area of a person with circulating antibody presents a complex *situation in* which cells abnormally accessible to infection are present as well as inflammatory exudative changes which will bring antibody into a position to prevent infection Whether infection occurs or not will probably depend on the *particular stage* that the eczematous process in a given area has reached when it is contaminated with virus In any case the process will be more limited than when a similar surface is infected in a person without any active immunity

There are still no real clues to the conditions which determine whether an area infected either primarily or secondarily will become the site of recurrent lesions. The fact that Kaposi's eruption in infants rarely gives rise to recurrent herpetic lesions in the eczematous skin area is in contrast to the present case, where an eczematous area was first involved in young adult life. It may be that a very severe primary attack resulted in the elimination of virus from the area, just as it appeared to be eliminated from the buccal epithelium, which bears the brunt of a primary stomatitis A combined study by dermatologists and virologists of the phenomena associated with herpetic infections in eczematous subjects of all ages would probably help to clarify the situation

SUMMARY

A case of recurrent Kaposi's varicelliform eruption is reported in an adult

Herpes simplex virus was identified as the infective agent, and antibody was detected throughout the course of the disease

The rarity of the condition in contrast to other forms of recurrent herpes is discussed

Our thanks are due to Dr Leslie Hurley for permission to publish this case, and to Dr A. Isaacs for assistance in the investigation

CLINICO-ANATOMICAL STUDY OF A SUCCESSFUL LEUCOTOMY

S DESMOND MCGRATH
M.R C P.I , D.P M
REGISTRAR, MAUDSLEY HOSPITAL, LONDON

From the Department of Neuropathology, Institute of Psychiatry, Maudsley Hospital, and the Department of Clinical Research, Crichton Royal, Dumfries

MANY successful results have been claimed for surgery of the brain in the treatment of mental disorder, and a considerable number of the patients so treated must have died since of intercurrent illness Attempts to determine whether there are optimal lesions for each type of case will require systematic correlation of the clinical data with the anatomical results of the operation in a considerable series of successful cases It is therefore a matter of great regret that up to now only one such case has been investigated and published (Freeman and Watts 1947)

I report here a second such case in the hope that it will not only contribute to a series of cases in the literature from which refinements in brain surgery may in due course be derived but will also draw the attention of doctors, especially pathologists in general hospitals, to the potential value of systematic investigation, at suitably equipped laboratories, of the brains of patients in whom leucotomy has been successful and who have died later from some other cause

CASE RECORD

Miss A, then aged 39, was admitted as a certified patient to Crichton Royal Hospital on July 26, 1937

Clinical History—Her mother had died after nine years' stay in a mental hospital because of a paranoid psychosis which had started with the menopause No other mental illness was known in the family The patient's development as a child was believed to have been normal She was a good scholar, rather reserved, and inclined to worry She was described as venturesome, difficult to advise, and self willed After some years at home she took up work in a public library, where she remained ten years In 1932 when aged 34 she left, because she thought that people were talking about her and were antagonistic to her She next trained and worked as a secretary for a short while, but in 1933 was admitted to a mental hospital for the first time with delusions of persecution auditory hallucinations impulsive behaviour, and incongruous affect She recovered sufficiently to be discharged in January 1934 She then worked as a typist, changing jobs frequently until March, 1936, when she had to be readmitted to a mental hospital, from which she was transferred to Crichton Royal in 1937

On admission she presented a typical picture of paranoid schizophrenia At first she seemed to have some insight into her illness, but soon she became overwhelmed by her delusional ideas which she extended to the hospital and the persons around her She was openly hostile towards her environment, accused her presumed persecutors of ill treatment, and was most of the time angry and withdrawn, often aggressive and violent She neglected her appearance and showed other signs of deterioration After a course of insulin coma therapy in 1939 she showed transient improvement and was well enough to index the medical library After a few months, however she relapsed into her former condition being completely self absorbed, inaccessible, and ill disposed towards everybody Electrical convulsion treatment applied in 1942 and 1943 produced only transient relief and was finally included in the patient's delusional system and refused

Leucotomy was done on May 16 1943, by Mr Alexander, using the standard technique of Freeman and Watts Immediate progress was smooth On the evening of the operation she was lucid and not confused She said she could still hear voices and that she had not changed at all After ten days she became incontinent of urine and fæces This persisted for two or three weeks and then gradually cleared Though the patient at first retained her delusions and hallucinations, she was less troubled and became noticeably more cheerful At times she was irritable and had rows with the staff and other patients By July of that year she could be given parole, and in October she went to work in the medical library However, owing to memory difficulties she could not carry out a projected revision of the library properly By February, 1944, she was efficiently doing secretarial work in the hospital and visiting her family at home for week ends She no longer expressed delusional ideas, and though when questioned she admitted that she still heard voices she said they were very faint and that she did not take any notice of them

After discharge on March 31, 1944, she got a job in a public library, where she worked satisfactorily Subsequently she was several times dismissed because of unpunctuality and lack of precision in her work, but on each occasion she very soon found a similar occupation For a time she was a librarian of a university institute, where she had much time to herself She decided to take her qualifying examination as a librarian and studied for matriculation, though now aged 47 She failed, but took this in good humour

Her condition improved progressively By the middle of 1946 she had become much more punctual and reliable, aggressive and unexpected changes in behaviour which she had shown after discharge became rare She led a happy and active life, and kept up an extensive correspondence with relatives and friends The long and chatty letters she wrote to her sister described her daily life with lively satisfaction She was considerate, friendly, and good company Only once, in 1947, did she mention in a letter her hallucinations, saying that she heard the voice occasionally but could ignore it

Though she had some difficulty in managing her money, being inclined to over generosity with presents and to sharing unduly expensive holidays, her sister said that the patient's ability to look after her affairs, and adapt to the great changes which had taken place in everyday life during her stay in hospital, was truly remarkable

She was disinclined to live and work in the small town near the hospital where she had been treated for many years, though her family would have preferred her to stay in the neighbourhood She came home, however, for short visits and was seen several times by the psychiatrist She was friendly and always willing to give information about herself, being neither over talkative nor reticent, and had full insight about her illness and the senselessness of her ideas of persecution For her treatment at the hospital she was thankful, but she attributed her recovery to the insulin therapy, not to the leucotomy Her memory of the sequence of events during the last few years of her stay in hospital was somewhat hazy

After leaving her last job as a librarian she became a secretary in the large outpatient department of a London teaching hospital, a post she held until her death from coronary thrombosis in December, 1948, at the age of 50, five and a half years after the leucotomy

Pathological Investigation

The brain displayed no abnormality of leptomeninges or superficial blood vessels The convex surface of the pre frontal region of each frontal lobe appeared moderately

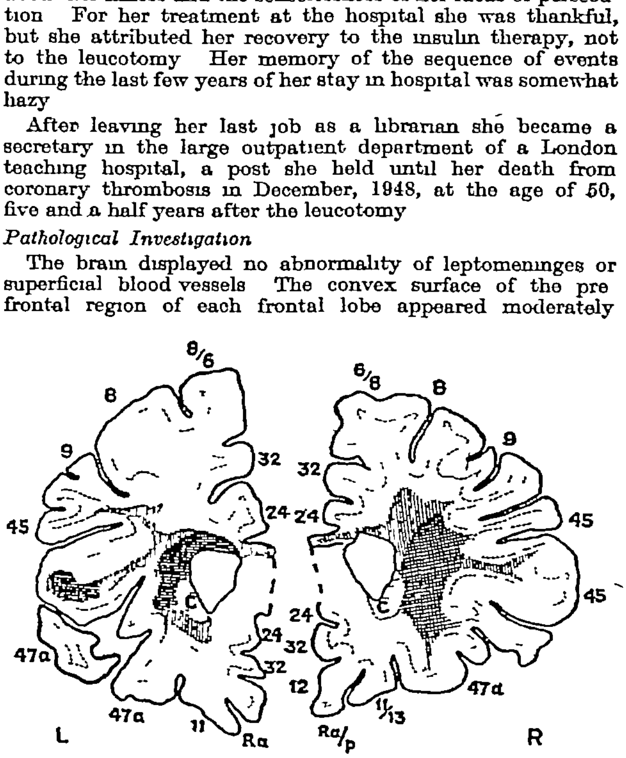

Fig 1—Coronal section of frontal lobes showing extent of leucotomy lesions (hatched areas) : C caudate nucleus

shrunken Otherwise the convolutions showed no abnormality beyond marks of the leucotome's entry on either side just rostral to the perpendicular branch of the sylvian fissure (anterior ascending ramus of the lateral cerebral sulcus) Coronal section through the two entry marks showed that the centre of each leucotomy scar lay at the level of the tip of the caudate nucleus (fig 1) On the right side the lesion took the form of a smooth walled cavity It cut at this level the whole of the central white matter external to the lateral wall of the anterior horn of the lateral ventricle, and the more superficial white matter related to Brodmann's areas 45 and 47 * The subcallosal fasciculus was damaged at the tip of the caudate nucleus The dorsal and cingulate segments of the white matter were not directly involved by the lesion, but the whole of the anterior thalamic radiation to the more rostral parts of the dorsal convexity were interrupted at the head of the caudate nucleus, which was only slightly damaged The ventricle and the main substance of the caudate nucleus had been spared

On the left side the lesion consisted of a more narrow slit The same regions of white matter as on the right side were involved, with the addition of damage deep to area 46 Both lateral ventricles were moderately dilated

Fig 2 indicates the extensive retrograde degeneration of nerve cells in the anterior, ventrolateral, and dorsomedial nuclei of the thalamus on either side as seen on examination of Nissl stained serial sections Reference to the scheme of parcellation of the thalamofrontal radiation described by McLardy (1950) shows that fibres to cortical areas 6, 8, 9 10, 11, 24, 45, 46, and 47 of Brodmann were cut Most of the fibres were cut as they emerged from the internal capsule, and the damage to the above mentioned thalamic nuclei was strikingly symmetrical The other thalamic nuclei were essentially *intact*, and there was no evidence of degeneration in the hypothalamus

DISCUSSION

The leucotomy seems clearly to have been mainly responsible for this patient's recovery from a paranoid schizophrenic illness of eleven years' duration, sufficiently severe to have required her continuous detention in hospital for six years before the operation Unlike her response to insulin coma and electric convulsion therapy her post leucotomy recovery of mental health was progressive and sustained The clinical change for the better was about as dramatic as his ever been reported in the literature The retrograde degeneration of nerve cells in the dorsomedial nucleus of the thalamus is about as complete, bilaterally, as has been described in any case of leucotomy The clinical result and anatomical findings are therefore fully consistent with the tentative conclusions reached by McLardy and Meyer (1949), from analysis of a series of cases with generally low grade improvement, that the quantity of prefrontal cortex isolated from thalamic and other long fibre connections should be directly proportional to the severity of the illness The general validity of such a "quantitative principle" has been confirmed for most of the other forms of surgical treatment of mental disease

That undesirable personality change was not a striking feature in the present case despite the posterior level of the cuts may be further evidence in support of Frankl and Mayer Gross's (1947) conception that the amount of damage should be calibrated to produce 'enough frontal symptoms to combat the symptoms of the psychosis—enough euphoria against distress and depression, enough extraversion and distractibility against introspection and withdrawal" Only a larger series of successful cases to compare with others developing undesirable personality changes can determine whether such a "neutralisation of symptoms" is the main factor in determining the final state A previous good personality which was a feature of this case, has been emphasised by Stengel (1950) and Partridge (1950) as a favourable prognostic factor

A considerable series of such successful cases must be anatomically as well as clinically followed up in detail if any principles are to be discovered of optimal lesions to create maximal improvement with minimal undesirable side effects On the anatomical side it is almost indispensable that the assessment of the lesions be made post mortem Meyer and his associates (Meyer and McLardy 1949) have repeatedly shown enormous discrepancies between surgical intention and necropsy findings after blind leucotomy, and now have some early evidence (personal communication) that even in the various open operations the surgeon's estimate of the extent of damage is not absolutely reliable for such correlation

SUMMARY

The clinical history of a severe case of schizophrenia of eleven years' duration, with recovery and survival for five and a half years after leucotomy, is reported together with a description of the primary lesions and the retrograde degeneration in the thalamus

The consistency of the findings with the general "quantitative" principle in the surgical treatment of mental disease is discussed briefly

This is only the second clinico anatomical study of a successful leucotomy that has been published The attention of doctors, especially pathologists in general

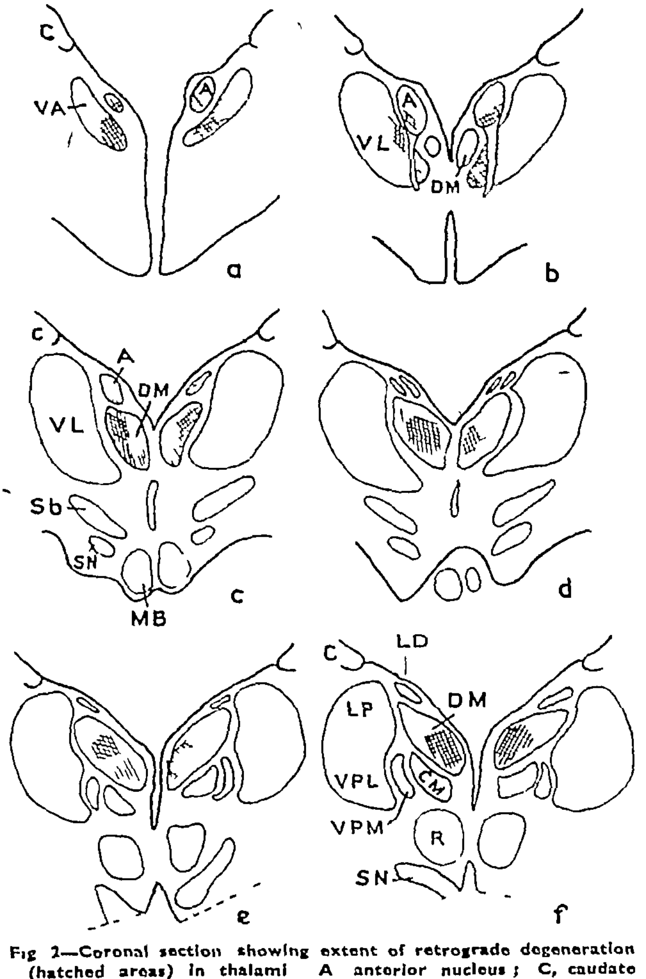

Fig 2—Coronal section showing extent of retrograde degeneration (hatched areas) in thalami A anterior nucleus; C, caudate nucleus CM centromedian nucleus DM dorsomedial nucleus, LD, dorsal lateral nucleus; LP, posterior lateral nucleus; MB, mamillary body R, red nucleus Sb, subthalamic nucleus SN, substantia nigra VA anterior ventral nucleus VL, lateral ventral nucleus VPL posterolateral ventral nucleus VPM, posteromedial ventral nucleus

hospitals, is drawn to the potential value of the brains of leucotomised patients who die outside mental hospitals.

---

* Brodmann's map of cortical areas is used here simply in virtue of its convenient topographical subdivision of the surface of the hemisphere

I wish to thank Prof A Meyer and Dr T McLardy for their interest and valuable criticisms, Dr W Mayer Gross for clinical notes, Mrs E Beck for advice, and Dr P K McCowan for permission to publish this case.

DELAYED PULMONARY COMPLICATIONS OF BRONCHOGRAPHY

Philip W Robertson
M.D Lpool, M.R.C.P

K. D Forgan Morle
M B St And, D.M.R.D

From the Department of Radiology, Royal Infirmary, Liverpool

In the course of investigations into various chest diseases between March, 1949, and December, 1950, we have done 220 bronchograms, mostly on young men, the method used being the introduction of iodised oil by cricothyroid puncture. No instance of classical iodism was seen, but 16 of the patients developed a delayed reaction one to two weeks after the bronchography. The reactions were pulmonary in type and were characterised by fever, cough, chest pain, and malaise. Five of the reactions were associated with pleural effusion. Urticaria followed the reaction in 4 cases, 1 of which also had transient swelling of the joints of the hands.

Few published references to this type of reaction have been found. Bass (1949) reports one similar case and he and Kooperstein (1946) had previously described 3 cases of delayed pneumonia following bronchography with iodised oil in asthmatic patients. Since so little has apparently been written about these reactions it seemed worth while to describe the clinical picture in detail, choosing the most severe case as an example. This bronchogram was done for control purposes on a healthy subject (one of us) and was entirely normal.

CASE REPORT

No ill effects whatever were felt after the left sided bronchography until the early hours of the seventh day, when the patient was awakened by a rigor. This was followed almost at once by abdominal pain, nausea and vomiting; indeed for the next few days abdominal discomfort and anorexia were the predominant symptoms. The patient felt extremely ill and had a temperature of 104°F.

Examination within a few hours of the onset of symptoms revealed signs suggestive of a pleural effusion on the left side. Cough developed in the next few hours, with scanty golden yellow watery sputum in which no pus or mucus was seen microscopically. The most striking feature of the sputum was the peculiarly uniform chemical yellowness. Laboratory examination showed that it did not contain any free iodine, but on spectroscopy it gave iodine absorption bands and the yellow material was proved biochemically to be an iodoprotein.

Chest radiography twenty four hours after the onset revealed a moderate left-sided pleural effusion with a considerable residue of iodised oil. In this case evidence of any associated inflammatory change in the left lung field in the vicinity of the iodised oil would have been obscured by the effusion.

Aspiration produced opalescent fluid of the same yellow colour as the sputum, containing a moderate number of eosinophils and a considerable amount of fibrin, sufficient to produce clotting, and found to be sterile on culture.

The blood white-cell count was 14,000 per c mm. with a slight polymorphonuclear leucocytosis; no preponderance of eosinophils was reported.

After three or four days there was no longer any fever or constitutional upset. The fluid was gradually absorbed and no trace was detectable radiologically after two and a half weeks. Furthermore, as the fluid was absorbed the residual iodised oil also disappeared, leaving a normal lung field. Subsequently there has been an entirely uneventful recovery.

OTHER CASES

The other cases have followed similar but less violent courses. Pleural pain, cough, yellow sputum, &c, have all occurred, and small pleural effusions were noted in 4 patients. In those cases which had an X-ray examination during the reaction, evidence of inflammatory change around the iodised oil was seen. In some, this consisted of a complete and uniform opacity maximal in the areas showing the most residual oil. In all cases there has been spontaneous, rapid, and complete recovery.

Several of these patients required a second bronchogram and it is interesting to note that where bronchography was repeated there was no recurrence of the complication. Indeed, a delayed reaction never followed a repeat bronchogram whether or not the first procedure was complicated.

We believe that careful observation of all patients after bronchography would reveal fever on or about the ninth day in an appreciable number. By retrospective examination of the temperature-charts of those patients who were retained in hospital for a sufficient length of time we have found that several had a short mild fever about the ninth day, with no significant symptoms.

DISCUSSION

The mechanism of these delayed reactions has not been determined, but despite the absence of any convincing allergic history, they are probably a manifestation of allergy. The constant time interval, resembling that of penicillin reactions, the eosinophils in the pleural fluid, and the urticarial eruptions are all suggestive. In view of the presence of an iodoprotein in the sputum of the affected patients, there may be an individual tendency to form this compound from the iodised oil, and it may then act as the allergen. In very few cases was there any associated lung sepsis and there was no evidence that a "stirring up of infection" occurred.

It is clear that patients should be carefully observed for a fortnight after bronchography. When the investigation is performed on outpatients they should be seen at the end of one and two weeks.

There does not appear to be any indication for treatment other than general nursing, in these cases. Antihistamine drugs may be tried but it is difficult to assess their effect owing to the rapid spontaneous improvement in untreated cases. Prophylaxis would presumably include immediate and efficient postural drainage after bronchography. All the patients in this series were given preoperative potassium iodide and no reaction to it was noted. Skin sensitivity tests were not performed.

SUMMARY

In 220 consecutive bronchograms there were 16 examples of delayed reactions, characterised by fever, cough, and malaise starting about nine days after the bronchography and lasting three or four days. In 5 cases there was a pleural effusion.

Rapid and spontaneous recovery was seen in all cases. It is suggested that the reactions are allergic.

All patients submitted to bronchography should be watched during the following fortnight.

We wish to thank Dr W S Sutton and Dr P H Whitaker for their helpful advice and criticism.

FATAL THYROID CRISIS

COMPLICATING TOXIC GRANULOPENIA DURING THIOURACIL THERAPY

A B Pollard
M D Lond , M R C P
PHYSICIAN, ESSEX COUNTY HOSPITAL, COLCHESTER

In a case of moderately severe thyrotoxicosis treated with methyl thiouracil a previous course of thiouracil had been given Shortly after the start of the second course toxic symptoms appeared, but thiouracil therapy was continued until three weeks later, when granulopenia developed In spite of appropriate measures the patient died within thirty six hours The clinical course of the final stage of the illness was remarkable in that the thyrotoxic symptoms were violently exacerbated, suggesting a thyroid storm or crisis

CASE RECORD

An unmarried woman, aged 25, was admitted to hospital on March 30 1949 Three years previously, after an emotional shock, she had had a nervous breakdown, with tremor of hands, fainting attacks, and outbursts of weeping At this time her neck was not swollen, nor were her eyes prominent Sedatives were prescribed, and after three months she improved considerably

A year later she had again become nervous and had noticed that her eyes were prominent and aching Her doctor diagnosed thyrotoxicosis, and for a year she was given thiouracil with no adverse reaction She improved greatly, losing her nervousness and gaining weight, but later, as her face became puffy, her hair fell out, and her neck was swollen, thiouracil was discontinued

Shortly afterwards a relapse had occurred, with return of the nervousness and loss of weight On this occasion she was given Lugol's iodine for a few months However, loss of weight continued in spite of a good appetite, occasional attacks of diarrhœa occurred, palpitations were troublesome, and weakness noticeable The exophthalmos and swelling of the neck persisted unchanged

The past history revealed nothing of note An interesting fact in the family history was that a sister had died of myasthenia gravis at the age of 24 This sister had had no goitre

On admission the patient was nervous and tremulous, of average nutrition, weight 7 st 13 lb , and height 5 ft 2 in , with a warm moist skin , bilateral exophthalmos with lid retraction , thyroid moderately enlarged (right lobe more than the left), smooth and firm, with no murmur or thrill , regular tachycardia with pulse rate 120, blood pressure 155/75, and sleeping pulse rate 116 Her heart was not enlarged , there was a short soft systolic murmur at the apex Nothing abnormal was found in the respiratory system or the alimentary system No weakness was detected in the central nervous system the reflexes were brisk and equal, the plantar reflexes being flexor

Investigations —Nothing abnormal was found in the urine The serum cholesterol was 140 mg per 100 ml The basal metabolic rate was + 40 (Benedict-Roth) A white cell count showed 7000 leucocytes (polymorphs 4200) per c mm Radiography of the neck showed a slight anteroposterior compression of the trachea at the level of D1, with possibly slight deviation to the left, but no side to side compression. No intrathoracic thyroid extension was visible The lung fields were clear, and the heart was normal in size and shape

Treatment and Progress —In view of the previous apparent good response to thiouracil, it was decided that further therapy with this drug should be given and that after a time the case should be reviewed particularly with reference to the advisability of surgical treatment On admission phenobarbitone gr $^1/_2$ t d s and a barbiturate sedative at night, if required, were prescribed From April 5 methyl thiouracil 200 mg t d s was given. Next day the patient's temperature rose to 101°F and she developed a generalised macular rash A white-cell count made at this time showed 5000 leucocytes (polymorphs 3450) per c mm On April 7 the temperature was normal and the rash had completely faded Methyl thiouracil was continued throughout in the same dosage

Over the next three weeks some improvement took place The tremor was less and the skin cooler The patient slept better and gained 4 lb in weight The sleeping pulse-rate was now about 100 The thyroid swelling and exophthalmos were unchanged However, she remained susceptible to the slightest emotional disturbance, and it was clear that at this stage she was by no means under the control of the anti thyroid drug Further white cell counts made during this period gave the following results April 13, 6000 leucocytes (2300 polymorphs) per c mm , April 14 5000 leucocytes (2300 polymorphs) , and April 16, 5000 leucocytes (2[illegible]00 polymorphs)

On the evening of April 26 the patient's temperature was 99°F Next morning she complained of a sore throat and headache Methyl thiouracil was discontinued forthwith. A blood count taken on the morning of April 27 showed Hb 75%, red cells 4,200,000 per c mm , white cells [illegible] (polymorphs 765) per c mm , platelets 150 000 per c.mm. Intramuscular penicillin 250,000 units was given four hourly By the evening of April 27 the patient s temperature had risen to 103 8°F and her pulse rate to 140 She was restless and agitated with respirations 40 a minute During the night the restlessness continued and her general condition showed a rapid deterioration Lugol's iodine 60 minims by mouth was given together with sedatives and an intravenous infusion of plasma Her restlessness became extreme urinary and fæcal incontinence developed, and her extremities became cold and cyanosed Her pulse, the rate of which had risen to 160, became increasingly weaker, and she died in the early hours of April 28 from cardiac failure During the last few hours of life the exophthalmos had become more pronounced The pulse throughout was quite regular

Necropsy —The body was that of a well nourished young adult female with protruding eyes The right side of the heart was slightly dilated The air passages contained blood stained mucus The lungs were emphysematous, with some areas of hæmorrhage and collapse, especially on the right side The bone marrow in the femur was slightly increased The spleen was somewhat enlarged, and the malpighian bodies were prominent The lymph glands were enlarged, and Peyer s patches in the gut were conspicuous The thymus was large, soft, and milky The thyroid was large and devoid of colloid The suprarenals contained little lipoid and showed an increase of brown pigment The bladder was empty, and the kidneys were slightly œdematous The uterus contained menstrual blood, and a small hæmorrhagic cyst was present in the right ovary No abnormalities were found in the central nervous system The orbital fat was much increased

Histological Examination —The heart muscle showed an increase of brown pigment Scattered groups of fibres had shrunken nuclei and hyaline sarcoplasm There were also scattered foci of chronic inflammatory cells, including numerous foamy multinucleated giant cells These were mainly distributed in the connective tissue and fat in the vicinity of blood vessels The kidneys showed cloudy swelling, with hyaline droplet degeneration in some tubules. The thyroid was hyperplastic, with vesicles usually of small size, mostly devoid of colloid, and lined by large and often columnar epithelium The orbital contents were composed of adipose tissue with scattered lymphocytes The lacrimal glands showed considerable lymphoid infiltration. The spleen was congested, and the malpighian bodies were enlarged The thymus was lymphoid Cultures made from material taken from the spleen at necropsy did not show any growth.

DISCUSSION

This unfortunate case is worthy of comment on two aspects The first question is the nature of the terminal illness The second is the wisdom of continuing the methyl thiouracil after the appearance of toxic symptoms —i e , fever and rash—a day after the start of the second course

The terminal stage of the illness was ushered in with fever, headache, and a sore throat These symptoms arising in a patient under treatment with thiouracil suggest a developing agranulocytosis with a throat infection In this case a severe granulopenia was in fact present Usually, after the administration of large doses of penicillin any infection is controlled, and this therapy, together with a complete withdrawal of the thiouracil, leads to a spontaneous and complete recovery, with a return of the granulocyte count to normal within a few days The rapid downhill course could have been due to a fulminating septicæmia, the organism being insensitive to penicillin in the doses given At necropsy, however, there were no signs of such septicæmia The extreme restlessness, tachycardia, and increase in exophthalmos suggested an acute exacerbation of thyrotoxicosis—the thyroid storm or crisis—and I suggest that this was the cause of death The crisis was probably precipitated by the throat infection which coincided with the granulopenia

The fatalities which have occurred with thiouracil have been due to agranulocytosis and infection Moore (1946), who reviewed a large series of cases of thyrotoxicosis treated with thiouracil with special reference to the toxic effects, found the incidence of agranulocytosis to be 1 74% and the fatality rate to be not more than 0 5% Since the general introduction of penicillin therapy the fatality-rate is probably even less Toxic symptoms are commoner with second and third courses of thiouracil, and tend to occur at an earlier stage of treatment They rarely appear before the seventh day, and 80% appear during the first six weeks' treatment with thiouracil (Himsworth 1948)

The thyroid storm or crisis is a highly fatal complication of thyrotoxicosis which has fortunately become much less common of late Himsworth (1948) states that the fact that the response to thiouracil is so good has meant the virtual disappearance of deaths from this highly fatal exacerbation of thyrotoxicosis McArthur et al (1947) describe 36 cases of thyroid storm out of 2033 cases of thyrotoxicosis admitted to their ward in twenty five years Of these, 25 cases followed operations on the patients, the remaining 11 cases occurred, in the non operated patients, from less easily identifiable causes. Psychological trauma or infection appeared to be the initiating factor in most of the cases These workers found that most cases of storm occurred in patients who had had the thyrotoxicosis for a relatively short time—i e , five years or less They were usually severe cases characterised by malnutrition and previous neglect Means (1948) considers that psychotic manifestations are ominous, and states that crises occurred particularly in those patients who did not show the expected improvement after treatment of their thyrotoxicosis

In the present case the patient had had the disease for about three years, and it was moderately severe Emotionally she was extremely unstable and she became further disturbed when she realised that a complication—i e toxic granulopenia—had set in Further, though it is well known that patients given a second course of thiouracil respond more slowly three weeks with methyl thiouracil in fairly high dosage had produced only slight improvement in her condition In retrospect it seems that an acute exacerbation of the thyrotoxicosis was not at all unlikely

Of the complications of thiouracil therapy, agranulocytosis is said to be the only dangerous one As regards skin rashes and fever due to it, Himsworth (1948) advises that thiouracil should be continued unless there is also a significant decrease in the number of polymorphs, and states that if the thiouracil is continued the fever disappears permanently Moore (1946) finds that drug fever and skin rashes occur in about 10% of cases and may be accompanied or followed by agranulocytosis McArthur et al (1945) consider that both fever and rash are certainly manifestations of drug idiosyncrasy, and Means (1948) states that the re exhibition of an anti thyroid drug to a patient who has shown a toxic reaction is contra indicated In the present case, since no granulopenia accompanied the fever and rash which developed twenty four hours after the start of the second course of thiouracil, the drug was continued Both fever and rash had gone within twenty-four hours, and no further trouble arose until three weeks later, when the granulopenia developed

SUMMARY

A fatal thyroid crisis in a thyrotoxic patient treated for a second time with thiouracil is described The crisis was associated with, and apparently precipitated by, a toxic granulopenia with a throat infection

Certain signs and symptoms suggested that an acute exacerbation might ensue , in the absence of granulopenia early toxic signs were disregarded, in accordance with current medical opinion in this country

In thyrotoxicosis that is at all refractory, or that seems likely to develop an acute exacerbation, any toxic symptoms from thiouracil should call for an immediate withdrawal of the drug and a recourse to iodine therapy followed by skilled surgery and more iodine

I am grateful to Prof G W Pickering for permission to publish this case, and to Dr D M Pryce for the necropsy report

Medical Societies

ASSOCIATION OF CLINICAL PATHOLOGISTS

THIS association held a meeting in London between Jan 25 and 27

Amidopyrine Agranulocytosis

Dr **GEORGE DISCOMBE** said that amidopyrine agranulocytosis was commonly caused by prescribing the drug in a proprietary mixture, the prescriber being ignorant of or forgetting its presence He had encountered 4 fatal cases , in 3 sulphapyridine was at first thought to be responsible, but amidopyrine had been taken at the same time It seemed probable that the action on the bone-marrow of sulphonamides and amidopyrine was synergic Three series of hospital and of rheumatic patients who received amidopyrine had been reported. Among altogether 960 patients in these three groups, there were 11 cases of agranulocytosis—an incidence of 1 1% This indicated that there was no justification for using amidopyrine in ordinary practice as an analgesic In Denmark the distribution of proprietary mixtures containing amidopyrine was forbidden , and it seemed probable that the same action should be taken in Britain Official figures did not provide an adequate guide to the frequency of drug agranulocytosis His impression was that there were about 50 deaths per annum in this country, although the Registrar-General's figures were somewhat lower He would say that some fatalities were undoubtedly misdiagnosed

Dr **E N DAVEY** referred to two cases The first was believed to be diphtheria but turned out to be an instance of absolute granulopenia, which was attributed to the taking of 'Novalgin' for ovarian pain , the patient fortunately recovered At that time Dr Davey had listed the proprietary preparations containing amidopyrine and had filled a whole sheet of foolscap The second case was in a school teacher who had all the appearance of having agranulocytic angina but turned out to have the anginose type of glandular fever This disease should be considered in the differential diagnosis

Dr **J C FORD** referred to the case of a ward sister who had been taking 'Cibalgin' for myopic headache She was admitted with severe sacro-iliac pain, was apyrexial, and had a white-cell count of 5200 per c mm , of which 35% were neutrophils This patient was allowed by her doctor to have some cibalgin for her pain, having previously been sensitised to this drug She died eleven days later, the hæmoglobin and red-cell count being unaffected throughout, but the total white-cell count falling to 400 per c mm

Dr C J C BRITTON could not reconcile the statement that commercial manufacturing firms were dissuading people from using drugs containing amidopyrine with the fact that he regularly received samples through the post Dr C W TAYLOR suggested that the best way to discourage the use of these dangerous drugs was to ensure that fatalities were properly reported at inquests Dr N SCHUSTER suggested that the simplest action would be to disallow proprietary names for amidopyrine Doctors should prescribe it individually so that they, and nurses, would know exactly what the patient was having Dr DISCOMBE had considered approaching the chairman of the Pharmacopœia Commission with this suggestion

Prof R J V PULVERTAFT said that he would advise prohibiting the use of any proprietary name As far as he knew there was nothing to prevent a firm changing the constitution of a preparation bearing a trade name He instanced a preparation which at one time had contained amidopyrine and had been responsible for several deaths It now no longer contained amidopyrine, but a preparation known by the same name was still on the market In almost every case of severe blood disease, and particularly in cases with purpura or aplastic anæmia it was essential to inquire whether a proprietary preparation had been taken

Prof D F CAPPELL agreed that the inclusion of amidopyrine in proprietary preparations should be prohibited by law He had met with fatal instances of agranulocytosis associated with the taking of a proprietary preparation before amidopyrine was dropped from its formula and he had seen others due to ' Allonal '

Other Subjects

Leucocyte Changes in Burns

Dr S SEVITT reported a study of the quantitative changes in the eosinophil, lymphocyte, and neutrophil counts in 26 patients suffering from burns involving from 0 1 to 80 % of the body surface Soon after burning the eosinophil count fell, reaching low or zero values in a few hours This was often accompanied by lymphocytopenia and usually by neutrophil leucocytosis (primary wave) The eosinopenia, which persisted from a half to seven days, lasted longer in those more extensively burned, and there was a statistical correlation between the percentage of skin-surface burned and the duration of eosinopenia Dr Sevitt concluded that eosinopenia was a sensitive index of adrenocortical activity in burns Other leucocyte changes described were the onset in some patients of eosinophilia following the eosinopenic stage, later or delayed eosinophilia probably being due to allergy, and a secondary neutrophil wave

Fallacies in Platelet counts

Dr W K TAYLOR said that platelet counts in cases of hæmolytic anæmia, using Lempert's method[1] were found to be unduly raised The error was assumed to be due to staining of the fragmented reticulum following lysis of the erythrocytes Elimination of the cresyl-blue resulted in platelet-counts which agreed with those obtained by the magnesium sulphate film method Lempert's urea-citrate mixture without the addition of dye should be generally used for platelet-counts If the field was not too bright, counting was quite simple

Normoblastic and Megaloblastic Erythropoiesis

Dr L G LAJTHA said that work with bone marrow cultures had yielded evidence of an inhibitory factor in the serum and cerebrospinal fluid (C S F) of patients with pernicious anæmia This factor inhibited the ripening of megaloblasts into normoblasts and produced megaloblasts from normoblasts in vitro Folic acid overcame the action of the inhibitory factor in vitro, and so did folinic acid (citrovorum factor) Crystalline vitamin B_{12} had no such effect

Biopsies in Rectal Disease

Dr C E DUKES pointed out that malignant disease of the rectum was seldom diagnosed without evidence of infiltration, and therefore some mucosa should be included in the biopsy In some cases of well differentiated tumours without infiltration a diagnosis of malignancy might not be possible

Kaposi's Varicelliform Eruption

Dr A DICK and Dr N R GRIST described 10 cases of Kaposi's varicelliform eruption which appeared at the time of the widespread vaccination occasioned by an outbreak of smallpox in Glasgow Of these 10 patients 4 were unrelated, 2 were members of the same household, and 4 were infected while in hospital No case had been vaccinated previously, and all had been in contact with recently vaccinated subjects and had suffered from skin damage In 5 cases which were investigated fairly fully the vesicle fluid showed numerous elementary bodies, cultivation of this fluid or of crusts yielded a coagulase positive *Staphylococcus pyogenes* in all, while in 3 the infection was mixed The material from crusts or smears was used to inoculate the chorio-allantoic membrane of 11 day chick embryos The vaccinia virus was isolated in 5 of the cases The evidence suggested that the causative virus (vaccinia in this series) was inoculated directly into previously damaged areas of skin 2 patients appeared to benefit by ' Aureomycin '

"*Adamantinomas*"

Dr K S THOMPSON and Dr L B MANLEY described normal tooth development briefly as a downgrowth from the ordinary squamous epithelium from the maxilla and mandible, and they drew attention particularly to the difference between the cells of the internal dental (enamel) epithelium and ameloblasts Many tumours, as in the tibia and pituitary, were wrongly called adamantinomas owing to the œdematous prickle cells, which superficially resembled stellate reticulum, the diagnosis of adamantinoma should rest on the developmental cell —the cells of the internal dental epithelium Since ameloblasts were present only with enamel, they objected to the name "ameloblastoma" for these tumours preferring "Thoma's adamantinoma", but because of long usage the term "adamantinoma" was better

Penicillin in Inflamed Tissues

Dr J UNGAR recalled that penicillin could be detected considerably longer in inflamed subcutaneous tissue than in blood In a further study bronchopneumonia was produced in mice and guineapigs by intranasal instillation of a virulent suspension of *Hæmophilus pertussis* When penicillin of different types (aqueous solutions of penicillin G or suspensions) was injected into the infected animals, it could be detected in the lungs in considerably higher quantities and for longer than in the lungs of normal control animals The peak of penicillin levels in the inflamed lungs was significantly higher than that of the blood-levels The tissue levels of penicillin depended on the type of penicillin injected (water soluble or water-insoluble) and the degree of infection in the lungs, the heavier the infection, estimated by the extent of lung consolidation, the higher were the levels of penicillin in the lung This was further evidence for the efficacy of single massive doses of penicillin in the treatment of acute infections One explanation of these findings was the increased binding of penicillin on the proteins (particularly the globulins) of inflamed tissue

Diagnosis of Weil's Disease and Canicola Fever

Dr J C BROOM described the customary methods for the laboratory diagnosis of leptospirosis These were isolation of the organism and the demonstration of antibodies, but with neither could the diagnosis be established early in the disease It had been found that, in the early days of the illness (1) the erythrocyte-sedimentation rate was greatly increased; (2) the C.S.F. contained an increased number of cells, even in cases which showed no symptoms of meningitis; (3) in the meningeal form of canicola fever the glucose content of the C.S.F. was increased; (4) biopsy specimens of gastrocnemius muscle showed the characteristic degenerative changes in single muscle-fibres or groups of fibres; (5) biopsy specimens of liver showed the characteristic loss of cord structure and also signs of regeneration. Sometimes the antibody titre for the infecting species was at first much lower than the corresponding titre for some heterologous species. This might lead to complications if a hitherto unrecorded species appeared to be implicated. In a recent case, however, the presence of heterologous antibodies helped to establish the diagnosis of Weil's disease in a patient who died while being treated with large doses of leptospiral antiserum, and who showed only a low agglutination titre to *Leptospira icterohæmorrhagiæ*.

---

[1] Lempert H *Lancet* 1935 i 151

[2] Ungar J *Ibid* 1950, i, 56

Epidemiology of Leptospirosis

Dr. J. M. **ALSTON** said that the illnesses and deaths in the British Isles known to be due to *L. icterohæmorrhagiæ* (Weil's disease) were roughly half those due to typhoid fever. The causal organism was excreted in great profusion by rats and, less, by dogs. Leptospiras did not survive long after excretion, and that was probably why the disease was limited to those people who, usually by occupation, were repeatedly or heavily contaminated by rat's urine. There was a seasonal increase of the disease in the autumn. The mortality-rate for 1949 and 1950 was 12% of observed cases. Death did not occur without obvious jaundice, and nephritis was the most lethal feature. In the non-fatal meningitic form of the disease, the glucose content of the C.S.F. was normal; infection during bathing tended to lead to meningitis. Reduction of case-mortality required early diagnosis so that penicillin and antiserum could be used to kill the leptospira before hepatitis and nephritis became severe.

The known incidence of infection by *L. canicola* in the British Isles in 1949 and 1950 was 25 and 33 cases. The source of infection was the urine of dogs. In man the disease was usually mild, with or without meningitis. Incidence was much higher in the second half of the year. The incubation-period and natural routes of infection were not certain.

Iron Metabolism

Dr. A. **KLOPPER** and Dr. S. **VENTURA** showed that the serum-iron fell significantly in late pregnancy. The changes in normal pregnancy were not nearly so gross as those demonstrated for the hypochromic anæmias of pregnancy; but they tended to show that the drain of iron during pregnancy caused latent iron deficiency. Serum-iron curves after oral and intravenous administration of iron showed that during pregnancy the intestinal mechanism of iron absorption was orientated toward a maximal transfer of iron to the blood stream; and that, when this mechanism was short-circuited by the intravenous injection of iron, the serum of the pregnant woman still showed enhanced power and speed in dealing with the influx of iron.

Myelomatosis

Dr. J. H. O. **EARLE**, Dr. N. H. **MARTIN**, and Prof. N. F. **MACLAGAN** described atypical flocculation tests in several cases of myelomatosis. Using a wide spectrum of flocculation tests, including the zinc sulphate (Kunkel) and ammonium-sulphate (Popper) tests, they found that, despite the raised globulin, only two cases of myelomatosis gave a positive thymol turbidity test; but seven gave positive ammonium sulphate tests, and two further cases gave completely negative flocculation tests. Cases with increased globulin but with negative thymol turbidity or other flocculation tests should suggest a diagnosis of myelomatosis.

Potassium Deficiency

Dr. G. K. **McGOWAN** said that the main clinical indications of potassium deficiency were: (1) muscle weakness leading to paralysis; (2) prostration, anorexia, and paralytic ileus; (3) alkalosis resistant to sodium chloride; and (4) electrocardiographic changes. He demonstrated particularly the shift from intracellular to extracellular potassium with the balance maintained by excretion in the urine and gastro-intestinal secretions; and he pointed out that potassium should not be given unless the renal function was satisfactory.

Estimation of Thyroid Function

Dr. J. B. **FOOTE** and Prof. N. F. **MACLAGAN** described an apparatus for estimating thyroid function by a modified radioactive test using iodine (I^{131}). By taking thigh counts and neck-counts they produced an index which appeared to have diagnostic significance in thyrotoxicosis.

Sir Lionel Whitby's presidential address and a paper by Sir Henry Cohen on the limitations of laboratory investigations have already been summarised in these columns.[3]

MANCHESTER MEDICAL SOCIETY

Oral Sepsis and Chest Infection

AT a meeting of the society's section of odontology on Jan. 22, Mr. R. H. R. **BELSEY** said that pulmonary suppuration and dental sepsis presented three separate problems: (1) pulmonary suppuration occurring spontaneously in patients with dental sepsis; (2) pulmonary suppuration following general anæsthesia in patients with dental sepsis; and (3) pulmonary suppuration following dental operations, with or without a retained foreign body in the bronchial tree.

By dental sepsis was meant "open" sepsis. The pulmonary lesions that might result were suppurative bronchitis, suppurative pneumonitis, lung abscess, empyema, and pyopneumothorax due to rupture of a lung abscess into the pleural cavity. The association was first emphasised by John Alexander, who stated that "no edentulous patient ever developed a lung abscess." The solitary lung abscess with sudden onset of symptoms that sometimes arose from dental sepsis suggested bronchial embolism by infected, particulate matter from the mouth.

The onset of pulmonary symptoms after a general anæsthetic or dental operation might be acute and fulminating; often there was a latent period of three weeks before these symptoms appeared, and this had masked the association of the two conditions. The diagnosis was confirmed by X-ray examination and bronchoscopy. Early diagnosis and prompt chemotherapy and physiotherapy might avert the need for surgical treatment, and greatly improve the prognosis. Modern anæsthesia with the commoner use of intratracheal tubes might have increased the risk of pulmonary infection from the mouth.

The falling incidence of lung abscess might be due to improved dental hygiene, and to educational and other factors such as the school dental service.

As a routine, dental sepsis should be eliminated at least three weeks before every elective surgical procedure under general or local anæsthesia. Intensive preoperative and postoperative physiotherapy, and chemotherapy were also important. Emergency operations should be preceded by thorough removal of all debris and infected tartar from the gums and teeth.

The elimination of pulmonary infection after dental operations could be attempted by careful preoperative oral toilet, by operating with the patient in the head-low position, by avoiding drugs that depress the laryngeal and bronchial reflexes, and by a penicillin "screen." Any patient suspected of having inhaled a foreign body should be examined radiologically as soon as possible, and if necessary submitted to bronchoscopy. Early diagnosis and treatment of pulmonary complications would prevent permanent lung damage. The removal of foreign bodies impacted in the bronchial tree for some days or weeks was rendered safer and easier by a preliminary course of intrabronchial penicillin. Awareness of the severity of the pulmonary complications that might follow dental operations should lead to greater attention to their prevention and to early diagnosis and treatment.

Reviews of Books

Thrombo-embolic Conditions and their Treatment with Anticoagulants

Charles D Marple, M D, assistant clinical professor, division of medicine University of California San Francisco, Irving S Wright, professor of clinical medicine, Cornell University Medical College New York Springfield Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 418 £3 5s

Here is a remarkably comprehensive and up to date account of the clinical use of anticoagulants The authors get off to a good start by emphasising the importance of thorough laboratory work Properly critical and sceptical, they nevertheless succeed in demonstrating how valuable anticoagulants can be if properly controlled and used, and it is to this clinical use of anticoagulants that the greater part of their book is devoted The contra-indications to anticoagulant treatment are given 17 pages The difficulties and disadvantages of treatment with heparin and dicoumarol are fairly considered and ways of dealing with them are clearly indicated, the fact that there are occasional failures is admitted and the reasons for them are adequately discussed In a final section of 100 pages on "recent advances" the use of anticoagulants in coronary thrombosis is fully dealt with, and there are short but pleasantly didactic and adequately detailed appendices on the laboratory methods used A list of 681 references shows that the published work has been adequately sorted, and altogether the reader could not find a better and safer guide through the jungle of anticoagulant practice

Recent Advances in Ophthalmology

(4th ed) Sir Stewart Duke-Elder, K C V O, D SC, F R C S, director of research, Institute of Ophthalmology, University of London, and ophthalmic surgeon, St George s Hospital, London, A J B Goldsmith, M D, F R C S, surgeon, Moorfields Westminster and Central Eye Hospital, and lecturer in ophthalmology, University of London London J & A Churchill 1951 Pp 372 28s

Sixteen years have elapsed since the previous edition of this book appeared, and the text has been completely rewritten Dropping some older interests and theories, the authors have chosen a number of subjects in which great progress has been made These subjects are the physiology and pathology of the aqueous humour, the use of the gonioscope and the fundus contact-lens in examining the eye, glaucoma, bacterial and virus infections, chemotherapy and antibiotics, physiology and pathology of the cornea, cataract, and endocrine exophthalmos Their approach is by way of physiology and pathology rather than surgery, and in each subject the present state of knowledge is summed up in lucid and readable style The profession will be grateful to them for this presentation of new thought—so much in so small a compass

Muscular Contraction

W F H Mommaerts, PH D, established investigator of the American Heart Association, Department of Biochemistry, Duke University School of Medicine, Durham, North Carolina New York and London Interscience Publishers 1950 Pp 191 33s

The last ten years have seen the most spectacular advances in the physiology and biochemistry of muscle This is largely due to work on the molecular form and behaviour of the structural proteins, but also to the extensive studies of the enzymes of the muscle cell and of adenosine triphosphate and all that has followed from its discovery Those who began to learn their physiology in the '20s were not taught about these matters, yet many of them are still keen to learn Dr Mommaerts's little monograph is just the thing for all who like to keep abreast of their subject, for it is short, clear, simple yet not dogmatic and delightfully historical in approach

The author first draws a picture of the metabolism of striated muscle as it has been worked out over the last thirty years, though he never hesitates to point out the unfinished appearance of parts of the canvas He goes on to deal with the muscle proteins in a similar way, describing their extraction, properties, size, shape, interactions—in short, their function as revealed by inspection and analysis A useful little summary ends many of the chapters Some of the terms—such as birefringence, and double refraction of flow—could be more simply explained when they are first mentioned and discussed, and a little more might have been said about contractile systems other than those of striated muscle But those who read the introduction are likely to finish the book, and they do not need a profound knowledge of the subject to enjoy it

Developments in Diphtheria Prophylaxis

Lewis B Holt, M SC, Wright Fleming Institute of Microbiology, St Mary's Hospital, London London Heinemann Medical Books 1950 Pp 181 42s

The production of diphtheria prophylactic of consistent antigenicity and constant composition is of great importance, and Mr Holt s book illustrates the immense amount of painstaking work this involves He has his own views about many of these problems, and on Glenny's depot theory of the action of alum precipitated toxoid he suggests that alum toxoids are physiologically excluded from the rest of the body fourteen days after inoculation Much of the book is concerned with P T A P (purified toxoid, aluminium phosphate precipitated) and there is an account of its use by Bousfield The book is too technical for the average reader, and the method of presentation does not make a difficult subject easier

The Neural Crest

Properties and Derivatives in Light of Experimental Research Sven Hörstadius, professor of zoology, University of Uppsala London Oxford University *Press 1950 Pp 110 15s*

In five short chapters, based on lectures given at University College, London, in 1947, Professor Hörstadius tells an absorbing story of experimental methods in embryology Most of us think of the neural or ganglionic crest as that part of the primitive embryo which goes to make the spinal root ganglia, but this is only one of its functions, for not only does it contribute to other parts of the nervous system but it also takes a diverse part in structural development elsewhere Thus excision and implantation experiments, as well as older methods depending on staining and serial section, show that it makes a major contribution to cartilage and cartilaginous bone, and even to membrane bone in the cranium. Experimental studies of the pigmentation of small amphibia and fowls are fascinating Professor Hörstadius describes how, when chick-embryo limb buds are transplanted, the development of a pigmented or a nonpigmented limb depends on the presence or absence of neural crest cells in the transplant The colour of plumage is also locally affected by later transplantations of cells of similar origin This dynamic embryology is far removed from the study of serial sections of our student days

---

Moveable-Removeable Bridgework (London Henry Kimpton 1950 Pp 221 56s)—This semi technical book, by Mr J O McCall, Mr I M Hugel, and Prof C F Bodecker is based largely on the writings of Herman Chayes, who was one of the foremost exponents of movable removable types of bridge for the replacement of teeth Part of the book is given up to Chayes's arguments and suggestions in favour of this type of bridgework, and technical procedures for making such types of bridge are described There is a great deal to be said for this kind of work, but its expense rather rules out its general application to the normal dental practice in this country

Bakteriologie und Serologie (Stuttgart Thieme 1950 Pp 644 D M 29 70)—This German textbook, one of the first on the subject to be published in that country since the war has excellent illustrations and makes wise use of numerous diagrams Lothar Hallmann is bacteriologist to the Heidberg Hospital Throughout the book he gives instructions in great detail and thus should be of special value to the beginner Many technical methods, such as how to use a microscope micrometer or how to do a complement-fixation test for trichina infection, will not be found in English textbooks of comparable size and descriptions of the pathogenic protozoa and viruses are included

THE LANCET

LONDON SATURDAY, FEB 17, 1951

Potassium Deficiency

We have learnt a lot in twenty years about the changes that occur in the body electrolytes in disease An enormous literature has grown up from the early work on the inorganic metabolism in Addison's disease and our ideas on sodium metabolism and the state of hydration of the body have certainly become clearer But in the last few years potassium has come to occupy the centre of the picture In 1940 the clinician s interest in potassium metabolism did not extend beyond the recognised changes in familial periodic paralysis and Addison s disease, and some isolated pieces of information such as the low serum-potassium in cases of alkalosis from pyloric obstruction, and the association of Cushing's syndrome with an alkalosis resistant to ordinary saline therapy and a low serum-potassium. Then in 1944 **Brown** et al[1] described attacks of paralysis with low serum-potassium levels in chronic nephritis, and a similar low-potassium paralysis was later described by **Holler**[2] in treated diabetic coma in both these conditions the paralysis was relieved by administration of potassium salts, and recent work has shown that the loss of potassium in treated diabetic coma is constant though paralysis is rare In 1946 **Govan** and **Darrow**[3] demonstrated a heavy loss of potassium in infants with gastro enteritis and claimed that treatment with potassium salts greatly improved their recovery rates Since then a wide range of conditions have been shown to cause a loss of potassium from the body These include uræmia treated with a Borst diet,[4] *p* aminosalicylic acid therapy,[5-7] partial gastrectomy[8] and many other surgical operations not always involving an escape of gastro intestinal fluids,[9] the use of ion exchange resins,[10] and those reported in these columns—idiopathic steatorrhœa (Dr **Lubran** and Dr **McAllen** last week, p 321), as a sequel to abortion and tonsillitis (Dr **Kjerulf-Jensen** and colleagues, this issue, p 372), and chronic nephritis (Dr **Davidsen** and colleagues, p 375). In Birmingham, Dr **Cooke** tells us on p 413, some 20% of patients with steatorrhœa develop hypokalæmia at some stage, and potassium lack seems to be a common immediate cause of death in the fatal cases The potassium lost in the stools comes, he suggests, from intracellular stores and is actively excreted into the gut

The major part of the body s store of potassium is in the cells, and the cells may be lacking in potassium when the serum potassium is normal, or even above normal if there is oliguria In severe cases of deficiency of cell potassium, particularly if a diuresis is produced by any means, the serum-potassium will also be low, it is probably the low serum potassium rather than any lack of muscle potassium that produces the electrocardiographic changes characteristic of potassium deficiency, the most notable being depression of the S-T segment and diminution disappearance, or occasional inversion of the T wave These E C G changes may be rapidly reversed if serum-potassium is restored to normal, long before the body potassium is fully replaced The E C G findings are the most constant sign of either potassium deficiency or potassium intoxication, and their value in diagnosis was strikingly illustrated by Dr **Hawkins** and colleagues last week (p 318) in their case of pyloric stenosis The other clinical manifestations of potassium deficiency are much less clear

In the light of all this evidence, how are we to recognise potassium deficiency, and if we find it, how should it be treated? The important factor in recognition is that we should bear in mind that it may arise in a large variety of clinical conditions, particularly those involving any disturbance of electrolytes or body water Potassium deficiency should be suspected whenever an unexpectedly poor response is obtained to saline therapy and any evidence of muscular weakness will reinforce the suspicion **Eliel** et al[11] describe a postoperative potassium-deficiency syndrome consisting in apathy, lethargy, nervousness, muscular weakness, abdominal distension and occasional ileus, disorientation, delirium, muscular twitching, and tetany, which is relieved by potassium therapy However, **Elkinton** and **Tarail**,[12] in a well-balanced review, say

> " It is difficult to establish the exact disorders of function which result from deficiency of potassium "
>
> " The evidence to date is inconclusive in respect to the specific benefit of potassium therapy to cellular function. The rationale of such treatment, therefore, depends principally on the ground that it is desirable to replace a substance in which the body is deficient. Potassium, like protein, is an essential constituent of the cells of the body, and replacement and prevention of loss of potassium is as logical as similar procedures in the case of protein Proof of this is difficult to obtain in clinical conditions with highly unpredictable prognoses

Chemical estimations of serum-potassium take several hours, where the laboratory is equipped with a flame photometer the result can be obtained quickly, but there are still not many hospitals in this country which have one, and an electrocardiogram will then often provide the answer most readily If suspicious symptoms are present and the serum-potassium is found to be low it seems reasonable to restore the serum-level to normal by the administration of potassium, but whether potassium should be given as a routine in all cases where deficiency is a possible complication, even when there are no clinical symptoms, is not yet certain where proper biochemical control is impracticable, the theoretical advantages of replacing the missing element rapidly must be weighed against the risk of potassium intoxication In any case, if the patient appears to be making normal progress, ordinary diet will replenish the body potassium within a reasonable time

When treatment is decided upon, potassium must be given in adequate amounts Since the greater part of the potassium is lost from the cells, the deficiency is much greater than is generally realised ELKINTON and TARAIL estimate that in an adult the lack may be from 228 to 936 m eq , or, in round figures, 8–36 g of potassium If the patient can take food by mouth, the potassium in his food may be reinforced by adding 80–120 m eq (say 3–5 g) to each litre of milk or fruit drinks , a mixture of the two potassium phosphates is more palatable than the chloride Provided there is a reasonable output of urine, potassium therapy by mouth is practically free from danger Alternatively, the potassium can be given subcutaneously, as was done by Dr HAWKINS and his colleagues, or intravenously If given with full understanding and adequate biochemical control either method is safe , but without these, parenteral therapy carries a great danger of potassium intoxication, an example of which was described by HAWKINS et al As a general guide, ELKINTON suggests a maximum infusion-rate of 20 m eq (0 8 g) of potassium an hour, in a solution with a maximum strength of 80 m eq (3 g) of potassium per litre A solution containing 4 5 g of K_2HPO_4, 1 g of KH_2PO_4, and 5 5 g of NaCl per litre, given at a rate of 300 ml per hour, fulfils these conditions

Parenteral potassium therapy is particularly dangerous in patients with a low urinary output Even in conditions such as diabetic coma, where a well-marked potassium deficiency is a constant finding, intravenous potassium should not be given unless there is a free diuresis , in the oliguric stage the outflow of potassium from the cells may exceed the capacity of the kidney to excrete it, and the serum-potassium, already above normal, may be raised to dangerous or even fatal levels by intravenous medication Here again the E C G may be of value in the presence of a raised serum potassium level the T waves become exaggerated, and eventually even P may disappear These findings are an indication for attempting to move potassium from the blood stream, rather than for adding to it Glucose is useful in accelerating the passage of potassium into the tissues, and saline helps not only by correcting dehydration but by producing adequate urinary flow After this flow has been restored is the time to start intravenous potassium therapy, if still needed

Vitamin-A Poisoning

ESKIMOS and arctic explorers have long recognised the toxicity of the liver of the polar bear and arctic fox Ingestion of such liver causes anorexia, nausea, vomiting, irritability, headache, and drowsiness, with scaling of the skin, starting around the mouth Ill effects from excess of vitamin A were observed experimentally by Japanese workers [1] in 1925 , and in 1943 RODAHL and MOORE [2] found that the liver of the polar bear contains about 20,000 I U of vitamin A per gramme RODAHL [3] later established that destruction of the vitamin-A content renders the toxic fraction innocuous MOORE and WANG [4] remarked that in the rapidly growing rat excessive doses of vitamin A predispose to fractures and intramuscular hæmorrhages, while in older animals the skeletal injuries are absent and death comes suddenly from massive visceral hæmorrhages The bleeding tendency was due to hypoprothrombinæmia, which could be corrected by the administration of vitamin K , but this vitamin did not affect the bone changes These findings have been confirmed in dogs [5] , skeletal maturation was accelerated with subperiosteal appositional growth of the cortex

The first account of chronic vitamin A poisoning in an infant was given by JOSEPHS,[6] who observed the condition in a boy, aged 34 months, who had received 240,000 I U of the vitamin since he was 3 months old TOOMEY and MORRISETTE [7] described a similar case, in which they noted cortical thickening of the long bones DICKEY and BRADLEY [8] noticed tender swellings and cortical hyperostoses in a girl, aged 3 years, who had had at least 400,000 I U of vitamin A daily for about 18 months ROTHMAN and LEON's [9] patients —a boy aged 14 months and a girl aged 22 months—had had about 120,000 I U daily for at least a year A further 10 cases have been recorded [10 11 12] In every proved case of such poisoning there has been a latent period of at least 6 months, and usually it is longer than a year When the condition is acute [2 14] the clinical manifestations are transient malaise, headache, giddiness, nausea, and vomiting , but the sequels of chronic poisoning are much more severe and persistent Sometimes pædiatricians have been unaware of the excessive intake until some time afterwards , and meanwhile the disorder has been mistaken for infantile cortical hyperostosis [13] The earliest manifestations are anorexia, pruritus, and irritability —symptoms so common in children that their significance may be overlooked Later signs are yellowish pallor , sparseness or coarseness of the hair , tenderness over the long bones, followed by swellings and limitation of movements , dry, scaly lips with bleeding fissures and angular excoriations , erythematous dry skin , hepatomegaly, rarely with splenomegaly , and a raised level of vitamin A in the blood In diagnosis great significance should be attached to tender swellings of the forearms or legs in an irritable, pale child with anorexia, pruritus, and possibly dry skin or cracked lips The swellings are most common on the forearms (perhaps owing to trauma) , they are never hot or œdematous , they are always firmly attached to deeper structures Radiography shows one single layer of periosteal proliferation, occasionally, irregular in outline, underneath the tender swellings , there is no undue thickening, and no lamellation (which is present with infantile cortical hyperostosis) Hyperostoses of two or more long bones have been identifiable in all cases since TOOMEY and MORRISETTE[7] first described this sign. The sites most commonly affected, in decreasing frequency, are ulna, metatarsals (with the exception of the first), clavicle, femur, tibia, fibula, and ribs.

According to CAFFEY,[10] vitamin A poisoning has only two features in common with infantile cortical hyperostosis—namely, cortical hyperostoses and tender soft tissue swellings. Infantile cortical hyperostosis has always made its appearance during the first 4 months of life (in one case it was present on the first day), whereas the effects of excessive vitamin A intake have never been recognised before the 12th month. No examples of either condition arising between the 5th and 11th months have been recorded. In every case of infantile cortical hyperostosis yet reported, the face, jaw, and especially the mandible have been thickened, whereas in no reported case of vitamin-A poisoning have these parts been involved. Metatarsal hyperostoses have been present in every case of vitamin-A poisoning in which the feet were examined radiologically, but in only one case of infantile cortical hyperostosis. The blood vitamin-A level is apparently normal in infantile cortical hyperostosis. Fever is the rule in infantile cortical hyperostosis, but it is absent in vitamin A poisoning, apart from transient fever due to intercurrent infection. Dramatic recovery—within 7–10 days of the cessation of excessive intake—is characteristic of vitamin-A poisoning, though the disappearance of radiological signs and restoration of normal vitamin A level in the blood may take many months; in contrast, the clinical course of infantile cortical hyperostosis does not change rapidly.

The mechanism of vitamin A toxicity is unknown. DAVIES and MOORE[14] showed that in animals symptoms depend not on the total amount of vitamin A in the body, but on the ingestion of amounts large enough to outstrip the ability of the liver to remove this substance from the circulation for storage. JOSEPHS[6] described the case of an infant, aged 8 months, who received 500,000 I.U. of vitamin A daily for 4 months without any toxic symptoms or rise of the blood level. Possibly impaired absorption of the oily solution of the vitamin during early infancy[15] may partly account for the absence of toxic symptoms in young babies receiving excessive amounts. On the other hand, hepatomegaly with increased serum alkaline phosphatase (which is found with impaired liver function) has been present in nearly all cases, and not only absorption of the vitamin from the bowels but also its release from the liver depends on normal hepatic function.[16] FRIED and GRAND[11] demonstrated hepatic dysfunction in both their patients. The symptoms were not, it seems, due to the vitamin D associated with vitamin A in the fish oil concentrates. The symptoms caused by excess of vitamin D are distinctive; and furthermore TOOMEY and MORRISETTE reproduced the clinical picture of vitamin A poisoning by administering the pure vitamin.

No case of vitamin A overdosage has so far been reported in this country, but now that we are aware of American experience an occasional case may come to light.

Methonium and Hypertension

EARLY reports leave no room for doubt that the methonium compounds are the most powerful hypotensive agents yet developed.[1 2 3] Unfortunately, with these as with most other drugs potency is matched by toxicity; the effective dose is often uncomfortably close to that which will do harm, and the right dosage has to be discovered afresh for each case. Furthermore, experience is still too short for clinicians confidently to select the patients who will benefit by sustained reduction of blood pressure.

Methonium can be given either by mouth or by parenteral injection; but most workers, including Professor SMIRK, who wrote last week (p. 346), and Dr. FRANKEL, whose letter appears in this issue, now think that oral administration is less satisfactory. At least in the early stages of treatment, the patient should preferably be treated in hospital. SMIRK[4] gives a trial dose of 15 mg. subcutaneously with the patient sitting up in bed, and then records the blood-pressure every ten minutes. Thereafter the dose is gradually increased, with injections two or three times a day. At first habituation is rapid; but after a few weeks some 200–250 mg. will usually produce a constant effect. The best method of assessing the result of each dose has to be decided by trial in every case; but normally the effect, which is maximal about forty minutes after the injection, is best judged with the patient sitting up or, if he is ambulant, standing. The aim is to secure a fall in blood-pressure to about normal, anyhow at the height of each dose's action, without evoking side-effects. These side effects, due to postural hypotension or blocking of autonomic ganglia, include faintness, dizziness or syncope, and dryness of the mouth, anorexia, nausea, abdominal distension, constipation, and mistiness of vision. Postural symptoms may be averted if the patient avoids standing still for any length of time—as, for example, in a queue—and if the foot of his bed is raised at night. Once present, such symptoms can be countered by the patient contracting his abdominal muscles, walking about, or lying down with the foot of the bed raised; if need be, ephedrine, adrenaline, or noradrenaline may be injected. With continuing treatment ill effects tend to become less troublesome, and it is usually possible to arrive at a dosage that is effective without causing more than very slight discomfort. Indeed, SMIRK's patients are taught to give themselves regular injections in the same way that diabetics inject insulin. The action of these compounds is enhanced by a low salt diet; and so is the risk of bromism.[5]

What of the risks of lowering the blood-pressure? These are still not clearly defined; but coronary or cerebral thrombosis may be precipitated in patients with advanced arteriosclerosis, and where renal function is impaired caution is clearly necessary. TURNER, who has outlined some of the dangers,[2] suggests in his letter this week indications for using these compounds. Until experience is greater, most workers will probably be content to limit their application to

severe cases (for example, malignant hypertension and hypertension with left ventricular failure), to short term disorders (such as toxæmia of pregnancy), to dangerous episodes (hypertensive encephalopathy), and to the relief of troublesome symptoms, such as headache, due to hypertension Only a long and carefully controlled trial can tell whether methonium may reasonably be given to the youngish patients with benign hypertension, with a view to postponing cardiovascular or renal lesions

"Prospect of War"

As soon as he steps outside his own field, the expert ceases to speak with professional authority For this reason CARR SAUNDERS and WILSON,[1] recommend the professions to abstain from pronouncements on the larger moral issues Lawyers, they say, should remain corporately silent on the ethics of capital punishment, and doctors on the ethics of euthanasia, for, as a body, they are no better qualified than other citizens to distinguish right from wrong On this view, no occupational group, except perhaps the Church, is entitled to advise the nation on how it should now face the risk of war, for no such group is a recognised authority on the relative morality of aggression, resistance, and submission Admittedly, expert opinion on matters of expediency may be acceptable and, just as the medical profession could properly explain that euthanasia has its practical inconveniences, it could properly describe the technical difficulties of tending the casualties of a new war But the expert's function, it is said, is to provide information quite objectively and only when asked to do so The structure of our specialised society demands that the cobbler shall stick to his last, and if a particular cobbler or doctor becomes convinced that euthanasia, or a large Navy, or friendly letters to the Kremlin, are what is now needed, he should write to his M P about it, as an individual citizen, not as a professional man

Sound up to a point, this doctrine could easily encourage excessive specialism, and we certainly do not think it should be allowed to narrow the scope of intraprofessional discussions THE LANCET has always regarded medicine as a very wide subject, and we shall continue to publish articles showing how the work of doctors influences and is influenced by the activities, ideas, and policies of other people Though we no longer emulate the catholicity of our early issues, we see no reason to pretend that doctors practise in a professional vacuum or are the better for restricting their vision Thus, at a time when everybody is profoundly affected by preparations for or against a possible war, we have thought it both permissible and right to allow expression of opinion to those of our colleagues who believe that the profession—though it may be no more than a small occupational group in the larger community—can make some special contribution to the attainment of peace The selection of letters published in the past few weeks under the heading "Prospect of War" reveals three reasons why doctors, as such, might claim a hearing on this subject The first is that, by tradition and training, they accept a supernational moral code which bids them help enemy and friend alike As the noblest of hospital mottoes has it, *Nihil humanum a me alienum puto*, and it is in this spirit that a correspondent bids the profession formally declare its neutrality in the internecine strife of men and rededicate itself to the service of all Secondly, by tradition and training, we are not only humanitarians but also scientists, who should think objectively and take a very long view As biologists we know that the differences between nations are transient and trivial compared with their common interests, we regard mutual aid as more important to human progress than the struggle for existence, and we recognise that the basic need is to tolerate and cooperate, not to condemn and destroy Thirdly, through the care of sick minds we have gained at least a little insight into the mental disorders that lead people to hate and fight each other Have we not learnt enough already to urge our leaders to beware of their emotions? Fear on the one hand, and anger on the other, are evil counsellors

These are reasons why doctors might think themselves qualified to make some corporate effort to deflect mankind from war But our correspondents give few signs of the necessary unity among themselves In the past decade many kinds of scientists have become anxious about the social implications of their work, and, just as the atomic physicists might decide that, whatever the cost to their own countries they would no longer devise instruments of destruction so the medical profession might declare that, in obedience to its higher code, it would take no part in military operations or civil defence But in fact since most doctors, like most scientists, are citizens first and moralists second, only a tiny minority would feel justified in taking direct action of this kind against the rest of their community Unless they are prepared to do this, the duty of doctors is plainly to give—and give freely—whatever expert help may be asked of them, for the very natural loathing of modern war felt by all civilised people does not by itself excuse any of us from answering the Government's call to aid in defence The knowledge that another war might be disastrous to all concerned is now very widely spread, but no response to peril is more futile than to rend one's raiment and utter cries of woe We can act in one way or we can act in another, but we should try to be clear about what we are doing Those who feel, with much reason, that what is above all necessary is to refrain from any action that promotes a war mentality should ask themselves whether in the last resort they are not depending on the defence measures taken by other people It is one thing to base noncooperation on a moral principle that nothing will shake, but quite another to base it on one's personal estimate of a political situation

Those who hold that the medical profession, as such, can advise its fellow citizens on the prevention of war have yet to explain what acceptable advice we humanitarians, biologists, and psychiatrists could offer without impertinence to a people who, though resolved not to submit to force, are almost as slow to wrath as they have been slow to arm If it turns out that, for all the sincerity of their convictions, the advice our colleagues want to give is primarily political, they must give it as citizens and not as doctors

PEPTIC ULCER IN OUR TIME

"IN the nineteenth century it was commonly believed that cooks and bootmakers were the most frequent sufferers from gastric ulcer, the theory being that cooks injured their stomachs by continually tasting hot and irritating foods while bootmakers pressed their stomachs against the boots on which they were working In the twentieth century opinion has been united in rejecting this belief, if in nothing else "

Having thus cleared the ground, a Medical Research Council report [1] sets out the results of a study—undertaken at the suggestion of Dr F Avery Jones, and sponsored by the council's Industrial Research Board—of occupational factors in the ætiology of gastric and duodenal ulcers

A Peptic Ulcer Coördinating Committee, under the chairmanship of the late Prof J A. Ryle and with Dr Joan Faulkner as secretary included Dr G R M Cordiner Dr C M Fletcher Dr H Gainsborough, Prof A Bradford Hill, Prof R E Lane, Dr W R S Doll, and Dr Avery Jones The last two with the help of Mr M M Buckatzsh, have been responsible for writing the report

Ulcers have been becoming commoner in hospital practice since the first world war, and according to a survey made in 1948 account for 10% of all adult admissions The committee found, from a review of published work on the subject, that it is generally agreed that transport workers are likely to have ulcers, and that rural workers, clerks, and sedentary workers are less prone to them than industrial workers and labourers But—apart from some figures relating to gastric ulcers among the fishermen of northern Norway—the statistical basis of most of these conclusions was "not such as to justify confidence being placed in them", so the committee started on a fresh survey

The types of occupation chosen for study included scientific research, light engineering, glass manufacture, goods transport passenger transport, civil service, hospital service, food marketing, the service and preparation of food, paper manufacture, and agriculture Firms and works' councils proved cooperative, and a list of employees was obtained from each firm or employer Those on the lists were seen first by a social worker, on whose report they were grouped under the headings "no dyspepsia," "minor dyspepsia," and "major dyspepsia ' A doctor then saw all those with major dys sia, and—as controls—10% of those with minor pepsia and no dyspepsia These controls numbered , and only 2 of them proved to have peptic ulcers social worker saw in all 5951 men and women , and 4 of these were referred for interview as cases of major spepsia Ulcer was regarded as proved if a positive gnosis had been made radiographically or at operation, if the patient had had hæmatemesis or melæna The idence of ulcer among 4871 men was 6 5% , and ong 1080 women, 7% The total number of ulcers ong women was so small that most of the rest of the iclusions were drawn only from men

The incidence varies with age, rising to a maximum 9 6% in men aged 45–54 and then decreasing Gastric d duodenal ulcers differ in age of onset, the expectation gastric ulcer being greatest between 35 and 64, while expectation of duodenal ulcer is greatest, and istant, between 20 and 64 No gastric ulcers were ignosed under the age of 25 The ratio of gastric to odenal ulcers in men was 1 2 2 , but the ratio rose ogressively with increasing age and with descent in e social scale The highest ratio was 1 1 2 over the e of 45 in the Registrar General's social classes IV and V

studying occupational difficulties the committee issified the men into 20 different groups , and the numbers of ulcers expected in each group was calculated from the figures for the whole survey, age being taken into consideration A significantly high incidence was found among doctors working in hospitals (15%, instead of the expected 6 9%) , but this is believed to be due to more refined standards of diagnosis among doctors If this is so, the committee point out, it must follow that the incidence in the general public is appreciably higher than estimated There was also an unexpectedly high incidence among a group of unskilled workers (11% instead of the expected 4 9%) , but here the committee had reason to think they were dealing with an excess of ulcer subjects who had sought out sheltered employment Apart from these two groups, high incidences were found among foremen and business executives, and low incidences among agricultural workers and—possibly—sedentary workers The theory that transport workers are specially prone to ulcer was not borne out drivers of motor vehicles and bus conductors had the expected incidence So did skilled engineering hands, electrical tradesmen, semi skilled workers in these industries, and heavy manual workers Irregular meals did not seem to have the baneful influence commonly attributed to them, but anxiety over work (not over home affairs) was more often complained of by those with proved duodenal ulcer than those with no dyspepsia, which is consistent with the view that men with the conscientious type of personality are particularly liable to develop duodenal ulcer Gastric ulcers are not found with greater frequency among the anxious, but they are related to social class, being commoner among the poorer than the well to do The committee draw attention to the deficiency of ulcers in agricultural workers, the social gradient of gastric ulcer, and the relation of anxiety to duodenal ulcer, as promising subjects for study

COCA-CHEWING

"I DON'T know whether to take a Benzedrine and go to the party or a Nembutal and go to bed " This is the issue before two young ladies depicted in the *New Yorker* The ingenuity of our new chemical industries, ably assisted by advertising, is creating new habits in drug taking Meanwhile old problems still exist among many peasant peoples accustomed to a regular supply of drugs provided by plants and shrubs growing freely in the countryside There are still large areas of the world in which many of the people have been life long addicts to either opium or hashish or coca These drugs have become part of the local way of life, and neither pharmacologist nor sociologist can assess with accuracy the effects of such addiction on individuals or groups

Coca chewing is practically limited to the Indian population living at high altitudes in the Andes , the habit is widespread among the inhabitants of the Altiplano in both Bolivia and Peru In our "Wider World" series Dr Passmore reported [1]

> Many in the Altiplano chew coca leaves throughout the day and can accurately be designated cocaine addicts It is widely supposed that coca enables a man to carry out hard work at high altitudes with greater efficiency and makes him insensitive to hunger, but that in the long run it leads to serious breakdown in both mental and physical health Yet many experienced observers both lay and medical, doubt the accuracy of these views I heard the opinion that coca chewing was, like tobacco-smoking, a dirty habit but had no serious effect on either health or working efficiency Statements both by individual observers and authoritative international conferences have mostly been adverse to coca "

At the request of the governments of Peru and Bolivia, the Economic and Social Council of the United Nations appointed a commission to inquire into coca-chewing in all its aspects The commission, who spent just under three months in Peru and Bolivia, have now published

Special Report Series no 276 London H.M Stationery Office 1951 Pp 96 2s 6d

[1] Passmore R *Lancet* 1949 i, 362

their findings.[2] On the pharmacological side it was found that opinions differed widely both on the usual amount of coca chewed each day and on the amount of cocaine extracted from the leaves. Prof. Gutiérrez Noriega stated that the daily dose of leaves varied between 10 and 100 g., with 30 g. as a mean value. The absorption rate from the bolus was found to be 80–90%, and a common daily dose of cocaine was 0.2 g. The leaves are usually mixed with some alkaline substance, such as quicklime or ashes obtained from burning grain; this, it is thought, increases the extraction rate. While the commission were clearly impressed by Professor Noriega's views, they point out that other pharmacologists do not set the figures so high; thus Prof. Aste Salazar estimates the daily absorption of cocaine to be usually no more than 0.005 g. The commission collected a bewildering variety of opinion as to the effect of chewing coca leaf, but they boldly conclude that the harmful effects arise primarily from inhibition of the sensation of hunger, which leads to constant malnutrition. The habit also induces in some people undesirable intellectual and moral changes which hinder the chewer's chances of improving his social and economic standards, mainly by reducing his capacity for productive work.

The commission were fully convinced that the main cause of the chewing habit was poor nutrition. Coca chewing offers escape from the misery of hunger; and where food is good, chewing stops. In many parts of the Altiplano present agricultural methods provide the peasants with a diet unsatisfactory in quality and often insufficient in quantity; and "the keynote of the whole action against chewing coca leaf can and must be the bettering of nutrition." At the same time there are other important ætiological factors, such as poor housing, general low levels of hygiene, and lack of education.

VOMITING AFTER MORPHINE

THE nausea and vomiting which sometimes follows the administration of morphine is usually ascribed to stimulation of the vomiting centre, and apomorphine, a closely related chemical compound, is the most powerful central emetic known. But it has been clearly shown that morphine vomiting largely depends on the position and movements of the body. Thus Lee[3] recorded nausea in 3% and vomiting in 2.6% of patients given an injection of morphine when lying in bed, whereas Comroe and Dripps[4] found that in people who were up and about the same injection produced nausea in 40% and vomiting in 16%, a finding that has often been confirmed in normal volunteers. It seems likely, therefore, that the vestibular activity accompanying body movement provides a suitable stimulus for a vomiting centre already made hypersensitive by the morphine. Rubin and Winston[5] have tested this possibility in normal people by injecting each with 15 mg. of morphine sulphate and then stimulating their vestibular apparatus either by spinning them round or by syringing their ear with cold water. When the 14 volunteers were given a preliminary injection of saline solution as a control only one complained of nausea and vomited after vestibular stimulation, whereas when the same people were given morphine vestibular stimulation caused nausea in 10 and vomiting in 6—indeed, 3 complained of nausea and 1 vomited before vestibular stimulation.

As every seasick traveller knows, excessive vestibular stimulation can cause vomiting in normal people, and the action of morphine seems to be to sensitise the vomiting centre so that it responds to the usually ineffective vestibular stimuli arising from normal body movements. One would expect this effect to be counteracted by hyoscine and other seasickness remedies. Rubin and Winston found that the antihistamine drug 'Dramamine,' now extensively used in the U.S.A. for the prevention and treatment of all forms of motion sickness, does prevent the nausea and vomiting evoked by vestibular stimulation after morphine, whereas amphetamine has no such action. Other antihistamine drugs would be worth trying for this purpose, and there may be some reason for continuing the traditional combination of hyoscine and morphine. Above all, however, it should be the rule never to give morphine to an ambulant patient—or hardly ever.

THE DOCTOR'S FRIEND

ANY complaint made by a patient against his National Health Service doctor is heard by the medical service committee of the local executive council, and in defending himself before this informal tribunal the doctor may, according to the regulation, have the help of some other person, "provided that no person shall be entitled in the capacity of counsel, solicitor or other paid advocate to conduct the case for any party by addressing the committee or examining or cross-examining witnesses."

The London Medical Service Committee have lately had a slight brush with the Ministry of Health over the interpretation of this regulation. A solicitor who attended an inquiry with a doctor was observed to be making copious notes of the evidence, and the committee who knew that legal proceedings were pending declined to permit him to remain. The solicitor appealed to the Ministry, which held that there is nothing in the regulations to prevent even a paid advocate appearing to assist his client or to take notes if necessary. The London committee, however, consider themselves a fact-finding committee which should not develop into a court "at which possibly counsel or solicitors would be appearing for both sides and would be prompting their clients to ask questions and cross-examine witnesses in much the same way as if the lawyers were conducting the examination themselves." They feel that the present regulation does not allow the committee enough discretion as to who may appear to help a doctor (or patient) at a hearing and to what extent counsel, solicitor, or other paid advocate may seek to influence the course of their deliberations. To this end they suggest that the offending regulation be amended to read "provided that no person shall be entitled to appear in the capacity of counsel, solicitor or other paid advocate." This would be a return to the wording of the old regulation governing this point of procedure in the old National Health Insurance committee.

In Northern Ireland legal representation of the parties before a service committee is not prohibited, and it has been suggested that the same procedure should be adopted in England, Wales, and Scotland. But the British Medical Association and the professional protection organisations have agreed that these investigations ought to be friendly and informal and not coloured or possibly frustrated by the introduction of legal advocacy which is appropriate to a court of law. Obviously the London Medical Service Committee also agree with this view, but they seem to have misconceived the underlying difficulty. The effect of their amendment would be to give the service committee power to forbid the attendance at the hearing of any persons other than (i) the complainant and the respondent doctor with their witnesses (if any), (ii) the secretary or other duly authorised officer or member of the local professional committee concerned (who might incidentally himself be a barrister or solicitor and in any case could take "copious notes"), and (iii) such officers of the council as may be appointed for the purpose (who might also be lawyers). There will be many cases where either the complainant or respondent is nervous, or deaf, or does not speak English fluently, when someone to assist in the presentation of his case would be helpful to the committee Again both parties have the right to appeal against the findings of the committee and the subsequent decision of the executive council Such an appeal is in fact a rehearing, but accurate and detailed notes of evidence given at the original hearing may be essential in deciding whether there are grounds for appeal or not

[5] Rubin, A., Winston, J. *J. clin. Invest.* 1950, 29, 1261.

Several questions arise. Who can take notes so well as a lawyer—unless it be some other "paid advocate"? Can the chairman of the committee, who is not necessarily a lawyer, decide whether a person assisting in the presentation of the case is a "paid advocate" or not? Does the London Medical Service Committee appreciate that it is the doctor who is the "accused," and that the complainant has nothing to lose whatever the outcome of the inquiry? These and other questions should be answered before the existing regulation, which has apparently worked well, is amended

FLUORIDE AND CARIES

SINCE the importance of the fluorine caries relationship was first appreciated numerous studies have been undertaken, notably in the U S.A , to discover whether artificial fluorination of drinking water will reduce the amount of dental caries It has been shown that, with a fluoride concentration in the drinking-water of 1–1 5 parts per million, the incidence of caries during the formative period of the teeth may be reduced by as much as 65% In 1945 three investigations into the value of artificially fluorinated drinking-water were started in the U S.A and Canada , and the results of one of these studies—at Grand Rapids, Michigan—have now been evaluated[1]

At Grand Rapids 1 part of fluoride per million was added to the public water supply, which previously had been fluoride free Analysis of the dental examinations in 1949 showed a considerable reduction in dental caries compared with the rate in 1944 and 1945 , and this reduction was most pronounced in the younger age groups, whose dentition was largely calcified after the fluoride was added It will be of interest to see whether the improvement is maintained. In this country Weaver[2] has shown that the effect of fluoride on the forming teeth, relative to caries resistance, seems to be somewhat evanescent , and that children with a previously low caries-count may in later life acquire more caries and have an average count despite the early and marked effect of fluoride That fluorination affords more than temporary benefit has still to be proved

ULTRASONICS IN TREATMENT

SOUND WAVES with frequencies between 16 and 30,000 cycles per second are audible to the human ear , but the frequency can be increased far beyond this range, and then the waves, being no longer audible, are termed ultrasonic That such ultrasonic waves can be produced by the relatively simple phenomenon of piezo electricity has long been known , and with the impetus of war this knowledge was swiftly extended

The medical application of ultrasonics has been investigated mainly in Germany and Austria The energy of ultrasonic waves can largely be converted to heat , and many effects produced by these waves can be attributed to the heat which is generated They can emulsify immiscible substances , but they can also reverse the process, for cumulative doses can demulsify Clinically, they are known to cause, in certain circumstances, oxidation and depolymerisation Their effects on living cells are very varied, extending from the known effects of heat to cavitation and vacuolation. The claims for their effect in treatment, however, seem to reflect enthusiasm for a new-fangled method rather than any encouraging accurate scientific observation One is reminded of the claims made for short wave diathermy when this was first introduced as a therapeutic agent, before it was recognised as fundamentally a form of heat treatment The conditions in which good results have been claimed for ultrasonics range from prostatic enlargement to otosclerosis , and much work has been done on the use of these waves in neoplastic conditions, without evidence of benefit Schliephake[3] claims that the field in which ultrasonics are going to be most useful is that of the "rheumatic" diseases but he does not define their indications or compare the effect of ultrasonics with that of more established procedures

An objective article by Nelson and his colleagues[4] shows the pitfalls which beset those ardently advocating a new physical agent such as this There seem to be few, if any, conditions which are not still better treated by other means In England the Ministry of Health has wisely limited the provision of ultrasonic emittors to certain hospitals, where critical physical and clinical trials are being carried out

DEPARTMENT OF HEALTH OF EIRE

DURING the union Ireland, unlike Scotland, had no special department of health, but was subject to the same code of laws as England and Wales, except that Ireland was specially excluded from part of it So on its formation the State of Eire took over a system of State medicine identical in theory with that of England and Wales, which it administered through a department of local government and public health, corresponding roughly to our deceased Local Government Board. In 1947 the government set up a new department of health to deal exclusively with health matters, and passed a comprehensive Health Act which fixed for Eire a form of health legislation somewhat comparable to that of England and Wales before the National Health Service Act of 1946 The Eire code of State medicine follows in the main the English code, but it departs from it in many details which are of great interest to students of the political and social aspects of medicine

The first report of the department of health of Eire covers the years 1945–49, but some of the statistical tables go back to 1925, and that of tuberculosis and cancer death rates to the beginning of the century Progress in health has been less than in Great Britain, for the disturbed state of the country between the two wars was a great hindrance to development Eire is developing a national health service , but this will not be developed along the lines of our National Health Service Act A notable achievement was the Mental Treatment Act of 1945, which gave to Eire an improvement on our Act of 1930 There is much to be learned from the growth of State medicine in Eire

THE British Medical Association has decided that it will not after all be able to take part in the joint meeting with the Medical Association of South Africa which was to be held at Johannesburg in July, "as an assurance cannot be given that all members of the British Medical Association will be free to enter South Africa" All will regret that the policy of the South African government has necessitated this decision , but we are glad that the profession in both countries has refused to compromise with the exponents of racial prejudice.

MINISTRY OF PENSIONS

In the later years of the 1914–18 war, the Ministry of Pensions became responsible for the supply of artificial limbs—and duplicates—to all pensioner amputees, and for maintaining the limbs in good fit and mechanical repair for the remainder of the patient's life

This was a revolutionary step not hitherto attempted in any other country, and it gave a unique opportunity to the group of limb surgeons formed by the Ministry of Pensions They were able to study an immense bulk of clinical material over a long period, from their observations they could decide what was the ideal stump for limb wearing at each site of amputation, and in so doing they could assist limb manufacturers in the evolution of the modern British prosthesis In no other country, until very recently, did doctors concern themselves directly with the art of limb fitting and collate and study the results obtained, and this professional interest may well be a cause of the acknowledged British supremacy in this field

The experience and knowledge gained by the Ministry's medical services in the treatment of war pensioners led to the extension of their work to civilians, and arrangements were made to permit this through the good offices of the governors of Roehampton (Queen Mary's) Hospital In the inter war years the limb service was much in demand by some of the railway companies and by many charitable organisations and local authorities During the 1939 war its work was increased by the schemes initiated by the Ministry of Labour for providing limbs for civilian amputees who needed them for return to work, and by the 1944 Education Act which enabled education departments to use the service for children of school age

From the outbreak of war until 1948, the Ministry of Pensions limb service bore the brunt of the supply, repair, and renewal of all artificial limbs required in this country for war casualties, past and present, working not only for the British Forces, but also for those of some of our Allies During this period 72,308 new limbs were ordered, including duplicates and renewals, and the Ministry's limb surgeons made 206,580 examinations

HOW THE SERVICE WORKS

In 1939 the Ministry's limb service consisted of 19 limb fitting centres situated at selected points throughout the country All were modelled on the centre at Roehampton, which was the hub of the organisation, and besides the medical equipment they included workshops and fitting rooms for the manufacturers of artificial limbs Each centre was a complete unit staffed by medical and technical experts with every facility for the supply and maintenance of the prosthesis The highest standard of workmanship, design, and material was, and still is, secured by a team of technical inspectors.

The routine of supplying a patient with a limb is not very different from that of the general hospital outpatient department The amputee is called by letter of appointment, and when he arrives he is taken to the limb surgeon for the prescription of the limb With the prescription he passes on to the contractor After some weeks, like any other patient, he receives his discharge and launches out from the limb centre fully ambulant on his artificial legs, or skilled in the use of an artificial arm He is advised to report by post, on a form, any defect in the limb either from the fitting or mechanical aspect On receipt of the form, the limb centre staff decide whether the patient must attend in person or whether, if only a mechanical repair is needed, the limb can be repaired and returned under a postal system The postal system can be used only by patients who have a duplicate limb, but it has proved its value in saving patient's time and avoiding abstention from work From the beginning of the war till the end of 1945, 79,240 patients attended for repairs, a further 110,095 repairs were dealt with by the postal system

RESEARCH

Every effort has been made over the years to examine and develop the constant flow of ideas from patients, manufacturers, and limb surgeons, and a fully organised research unit, with trained technicians and draughtsmen, under the charge of a limb surgeon who also has engineering qualifications and experience, has been a feature of the Roehampton organisation for some years This unit works in close collaboration with the limb fitting surgeons throughout the country so that interchange of opinion between the clinical and technical side of the *service is a recognised procedure* Among the many problems now being studied are the benefits of the suction socket limb, which is retained on the stump without supplementary attachment to the body, the cause and treatment of pain in amputation stumps, the effects of amputation on blood pressure, and the choice of disarticulation at the knee for elderly patients.

THE LIMB SURGEON

Having thus outlined the main fabric of the service, we can best give an idea of its intricacies by describing the duties of the limb surgeon

This officer is specially trained in the art and practice of limb fitting He first undertakes a course of instruction at Roehampton covering the treatment and preparation of the amputation stump for limb wearing, and the *recognition of individual idiosyncrasies* in the amputee, the special needs of children, and the æsthetic requirements of women He studies the methods of training in the use of limbs and the supply and use of appropriate additional appliances for the amputee with artificial arms

Methods of training in the use of artificial limbs include stump muscle re education, remedial exercises to improve joint mobility and stump control, the acquirement of balance and the development of confidence in the ability to wear the artificial limb This entails the practising of everyday movements—such as, for a leg amputee, turning, stooping, sitting down, walking up and down stairs, and walking on a cambered surface and over rough ground The arm amputee reaches the goal of occupational efficiency by training in the use of the various appliances

On completion of this course, which lasts from two to three months, the limb surgeon assumes responsibility for the continued rehabilitation of the amputee from the time the operating surgeon considers his work complete. In many cases this transfer of responsibility is decided in consultation between operating surgeon and limb surgeon In the absence of this ideal arrangement, the limb surgeon makes a detailed examination in order to assess (*a*) the functional value of the stump, and (*b*) the patient's general physical and mental capabilities This first contact is important, for on the proper briefing of the patient will largely depend his sense of confidence and his morale The limb surgeon then prescribes any treatment still required to render the patient fit to wear a limb The stage at which limb fitting commences is at his discretion At the appropriate time he prescribes the prosthesis in detail giving instructions as to the type of limb, whether of metal or wood, the method of suspension, and so on The choice of prosthesis must depend on the physical condition of the patient, his mental outlook, his probable future occupation, and even the climate and nature of the country in which he is likely to live In special cases, the limb surgeon supervises the fitting at all stages, and in every case he is responsible for ensuring that the completed limb is satisfactorily fitted

EFFECT OF THE NATIONAL HEALTH SERVICE ACT

When the National Health Service started in July, 1948, a ready made and nation-wide artificial limb service was already in operation and working smoothly The limb service had supplied over 200,000 limbs to amputees from the Services, from industry, and from private and other organisations It had acquired a world wide reputation, and the Roehampton limb centre had become the mecca of all those visiting this country and interested in prostheses The service was well qualified, therefore, to supply limbs to those needing them in the general population The machine, already in motion, only had to be geared up to meet the imponderable demands likely to be made A great variety of clinical problems suddenly streamed into the limb centres elderly amputees and children with congenital deformities mixed with the war wounded and eventually outnumbered them. Table I gives some idea of the size of the problem set by these new civilian patients

TABLE I—WORK OF THE LIMB SERVICE FOR THE N H S

Year	New legs ordered	Repairs to legs	New arms ordered	New mutilated hand appliances ordered	Repairs to arms ordered	Surgeons examinations
1948–49	13 670	15 754	2291	245	1028	41 398
1949–50	14 297	21 952	2239	321	1647	61 279

Of the 27,967 new legs ordered for National Health Service cases in the past two years, 77% have been metal ('Duralumin'), 22 99% wood, and 0 01% leather In the light of these figures it is interesting to recall that Muirhead Little [1] wrote in 1922

> The battle of the legs is still raging and at the moment aluminium seems to be in the ascendant over wood and leather, it must be remembered however that the two latter have been exposed to a length and severity of proof to which it has not yet been possible to subject the former

The increase of work after the appointed day was foreseen and appropriate dispositions made Thirty one additional limb surgeons had been trained and were posted to centres where large populations suggested there might be early and urgent requests for prostheses The existing limb centres, both at Roehampton and in the provinces, were enlarged where necessary and several new centres were opened or put under construction At Roehampton and Leeds where the limb centre is at a Ministry of Pensions hospital arrangements were made for the allocation of a number of hospital beds for civilians who were in need of further stump treatment, more advanced rehabilitation, or special study and care in the fitting of a limb

TABLE II—REVIEW OF 81 PATIENTS OVER 65 YEARS OF AGE ADMITTED TO QUEEN MARY S HOSPITAL ROEHAMPTON FOR LIMB FITTING OR WALKING TRAINING

Age in years	Result of fitting and training				Total
	Satisfactory	Failure	Death	Incomplete	
65–70	21	9	1	4	35
70–75	10	6	2	2	20
75–80	10	7	0	3	20
over 80	4	1	0	1	6
Total	45	23	3	10	81

Satisfactory = Regular use of prosthesis for at least three months after completion of walking instruction

Failure = No use made of prosthesis after walking training or attempted training

Incompleted = Limb fitting or walking training not yet complete or 3 months not yet elapsed after termination of training

These figures represent only those elderly patients whose admission to hospital was essential

It is an axiom that the limb surgeons' work is irrevocably linked to the capacity of the manufacturers to produce limbs, and unfortunately the supply of limb fitting technicians, whose training is a lengthy and difficult affair, has not kept pace with the demand for artificial limbs For this reason some delay in the supply of new limbs has been inevitable, but this is now being steadily overcome

The new régime has brought no fundamental change of policy But the consciousness of widening responsibility has sharpened Greater attention than formerly has been paid to the principle that the greatest benefit to the patient is most likely to accrue from joint consultation To this end steady and successful efforts have been made, and will continue to be made, to create a firm liaison, founded on mutual respect, between the orthopædic surgeon and the limb surgeon

EXPERIENCE OF THE PAST TWO YEARS

The Elderly Civilian

To the limb surgeon of the Ministry of Pensions, accustomed to the supervision of the patient from the earliest possible moment—often from the moment the decision to amputate was taken—it has been disquieting to find patients at the limb centres, certified as fit for limb fitting who cannot stand on the sound leg or even use crutches Again, patients in whom exercise tolerance is so impoverished that their prospects of training are negligible have come with requests for artificial limbs It cannot be too strongly emphasised that such a patient has no prospect of walking on a prosthesis with safety The risk of collapse during the severe physical effort and mental strain of learning to walk on an artificial limb is very real in elderly patients, and deaths have occurred (table II)

To convince patients that the prospects of walking are remote and the risks are great is well nigh impossible when operating surgeons have earlier implanted an over sanguine and self sufficient attitude The need to encourage the prospective amputee to help him overcome his apprehension and revulsion at the thought of amputation is paramount, but when dealing with elderly and enfeebled cases, whose prosthetic success is clearly problematical, encouragement as to future limb wearing should be given with the utmost reserve, with a leaning toward the greater possibility of a wheel chair If, later, limb fitting is found to be possible without undue risk so much the better for the morale and the contentment of the patient

Single Amputees

Tables III and IV give the results of a survey of a random sample of 1658 lower limb single amputees and

Over 70	3	1	0	1	5	0	3	0	13

287 upper limb single amputees classified according to age groups and cause of amputation

Double Amputation

The incidence of double amputations of the lower extremity is higher in civilian practice than among war amputees These amputations are largely caused by cardiovascular disease accompanied by varying degrees of debility Limb fitting, when possible, is a longer process calling for patience, stoicism, and determination from the patient The double •above knee amputee makes his first steps on short peg legs upon which balance is learned while there is but a short distance to fall In this way confidence is acquired, flexion deformities are reduced, and general physique improved From these pegs, the more promising may graduate in time to full length legs after a further period of training, the whole process may take upwards of a year to complete If patients were told of these prospects from the outset, much of their impatience, which reacts so strongly against their cooperation during the early tedious stages, would be forestalled

Table V shows the age incidence of double leg and double arm amputations

Malignant Disease

Young patients, who have been amputated for malignant disease are in a different category Despite the doubtful prognosis it is considered inadvisable to withhold a prosthesis until the risk of secondary deposits can be excluded To do so would be equivalent to informing the patient of the diagnosis It is the practice to prescribe a limb for these patients at the earliest opportunity and to begin at once the fullest course of training consistent with the patient's general condition The prognosis is so clouded—many survivors living a great number of years—that this policy is considered fully justified despite the disappointment of some early deaths

TABLE IV—CAUSES OF SINGLE ARM AMPUTATIONS AND AGE INCIDENCE IN 287 PATIENTS

Age in years	Trauma	Osteomyelitis	Congenital	Tuberculosis	Cardiovascular	Diabetes	Other diseases	Unknown causes	Total cases
Under 11	5	0	31	1	0	0	0	10	47
11–20	19	0	12	1	2	0	0	5	39
21–30	33	0	8	0	0	0	2	8	51
31–40	41	2	6	0	1	0	2	8	60
41–50	34	0	5	1	0	0	2	14	56
51–60	14	0	2	1	0	1	4	5	27
61–70	2	0	1	1	1	0	0	2	7
Over 70	0	0	0	0	0	0	0	0	0

PSYCHOLOGICAL REHABILITATION

Successful rehabilitation of the limbless depends upon the correct psychological approach from the time of amputation onwards The loss of a limb is a severe psychological trauma followed by anxieties and mental disturbances of varying types depending upon the personality of the patient Some compensation can be offered by explaining to the patient how much he can still hope to do, at the same time indicating activities which must be curtailed He should be impressed with the fact that every amputee can be a useful member of society *and that the loss of a leg or legs does not* foreshadow crippledom

Arm amputees should be encouraged to use their stumps at the earliest moment after amputation and thus develop the idea that the stump will be a useful member All amputees want to be independent and they should not be frustrated by too much unnecessary assistance, which easily tends to convince them that they really are cripples An amputee should be allowed to help in the hospital ward If he has lost a leg he should be encouraged to get about soon on crutches

Suitable stump exercises and correct bandaging should be begun as soon as possible, and the patient should be told that by conscientiously carrying out his treatment he will obtain a limb the sooner

Training in the use of a limb, especially an artificial arm, is most effective when carried out in a limb centre Not that any revolutionary methods are adopted, but rather that the stimulus to the amputee of being trained with others similarly disabled, and by those who have specialised for years in the training of the limbless, has proved so valuable as to be almost indispensable. The instructors moreover, are all trained in artificial limb design and fitting and have long experience of the exertions entailed, and can temper their demands upon patients according to their knowledge Again, during the training period, small adjustments to the fit of a socket are often found necessary, and in the limb centres the contractors' fitters are available to carry out these without retarding the training Full details of training methods have recently been published by the Ministry of Pensions.[2]

TABLE V—AGE INCIDENCE IN 128 DOUBLE AMPUTATIONS

Age in years	*Double leg*	*Double arm*
Under 11	12	2
11–20	14	1
21–30	20	3
31–40	16	1
41–50	31	1
51–60	22	2
61–70	3	0
Over 70	0	0

Arm training can only be given in a properly equipped arm training school, whose instructors are themselves arm wearers Unless purely cosmetic function is required, which is rare, the provision of an artificial arm without training is a waste of time and money

CONCLUSION

The most important lesson of the past two years' experience of artificial limb supply is that the closest liaison between the orthopædic surgeon and the limb surgeon is an indispensable prerequisite to complete *rehabilitation of the amputee*

This collaboration should be engaged at all stages, and consultation should, where possible, take place before amputation It can be fostered by more frequent requests from the orthopædic surgeon to the limb service for joint discussions and by fuller recognition of the difficulties with which limb fitting and rehabilitation abound

The limb surgeon must recognise that both the amputation and the resultant stump are but one aspect of a major disorder which requires closer supervision In many cases new ideas in rehabilitation and in the maintenance of well being and good function of the stump must be constantly sought

A plea is also made for combined operations in research so that all the resources of modern technique be used to improve the structure of the artificial limb and to fortify the patient's capacity to wear it

We are indebted to the Director General of Medical Services for his permission to publish this paper

THE REGISTRAR PROBLEM

N J Logie

MB Aberd, FRCS

The future of the many registrars threatened with dismissal by the plan announced last November[1] is still in doubt, but, judging by a statement to which its representatives have agreed,[2] the Ministry of Health is coming to recognise that this plan was too ruthless

Bearing in mind the acknowledged shortage of consultants and the difficult position in which registrars are now placed, several courses are possible

Additional Consultant Posts

The service needs further consultants, though how many will not be clear until the present survey of hospital staffing is completed The ideal number cannot, however, be achieved at once, owing to several factors of which financial stringency and lack of suitable accommodation are perhaps the most important, and it behoves consultants to ask themselves whether they really can justify retaining all their appointments and/or sessions If they cannot, they should surrender some and thus make room for the upgrading of registrars

Creation of a "Specialist" Grade

The formation of a "specialist" grade, intermediate between those of registrar and consultant seems desirable on more than one count

1 It would end the uneconomical situation in which the few highly trained handpicked survivors of at least five years competitive training may be flung away (to be replaced by other future victims) at the end of their third or fourth year as senior registrars because no consultant post is immediately available The new grade might be one into which exceptional senior registrars could be fitted should no suitable consultant post be vacant at the time, and if the amount of work was then insufficient, another senior registrar might not be appointed for the time being

2 Not all specialties require that each of their 'permanent officials' be of full consultant status At present to cover the work registrars are used and abused, or conversely consultants do work which could be done by less experienced and less expensive personnel

3 With a group of specialists on which to draw, there would be less risk of not finding a suitable candidate for a consultant post As things are when no suitable candidate comes forward, either an unsuitable consultant appointment is made or else the work is passed to a senior registrar or to a senior hospital medical officer (S.H.M.O)

4 This step would save valuable personnel for the service

5 It would open the way to abolishing the unpopular S.H.M.O grade

6 It would increase the number of posts open to senior registrars

7 It would lead to a reduction in the number of senior registrars, for these specialists would do much of the responsible work now done by senior registrars, who should properly be regarded as trainees

The "specialist" should be given security, suitable status, and an adequate salary (intermediate between that of registrar and of consultant)—none of which a registrar has—while he is furthering his experience or awaiting a consultant post

Two provisos would have to be fulfilled (1) the full consultant needs of the service must be decided on, and (2) the creation of the "specialist" grade must not be used to whittle down the consultant establishment

OTHER OPENINGS

Nowadays opportunities are few for the general practitioner who seeks to specialise, and entry into general practice is especially difficult for ex registrars For those registrars who fail to secure a consultant post these obstacles should be removed

The General practitioner Specialist

There are small hospitals in many townships which are at some distance, or which are not easily reached, from the nearest large centre In these hospitals there is still a place for the man who can deal, for example, with emergency surgery and the simpler surgical problems In such an area the ex registrar should be enabled to learn something of general practice by working as an assistant in a practice for a year before taking it over, while in a partnership practice his initial lack of knowledge would be covered by his partners The scope of his specialised work would be deliberately restricted, and the number of patients on his general practice list would be limited, in order (*a*) to allow him time for his specialised work, and (*b*) to prevent him, or the partnership to which he belonged, from taking advantage of his hospital post by attracting an unfairly large number of patients The local hospital would have the consultant services of a parent hospital behind it

Training for General Practice

The more senior registrars who fail to gain advancement and who wish to enter general practice should be helped to find assistantships or, better still, trainee posts During the period of training any difference between the ex registrar's former salary in hospital and his earnings as an assistant should be paid either by the former employing authority or from a special fund The value of this system would be enhanced if refresher courses were offered to those about to enter general practice

[2] See *Brit med J* suppl Jan 27 1951 p 24

DOMICILIARY CONSULTATIONS

In future the domiciliary consultant service is to be operated entirely by regional hospital boards, boards of governors having no hand in its organisation This is announced in a Ministry of Health circular (R H B [51]11) which also states that consultations should be arranged by the family doctor directly with the consultant and not through the regional board

The circular, reviewing the operation of the service in the past two and a half years, remarks that local health authorities are responsible for securing that mentally ill or mentally defective patients are brought under care

As regards the domiciliary service under the National Health Service Act, the intention is that a consultant (or, where there are not enough consultants, a senior hospital medical officer) shall be available for domiciliary consultation or treatment when the family doctor considers that the patient's condition makes it essential for this to take place at home. Here "home" means the place where the patient is for the time being resident, but it does not ordinarily include a private nursing-home

'The domiciliary service will however, be available to persons who live (i e, are bona fide residents as are some old people) in private nursing homes, and visits by obstetricians or pædiatricians (accompanied by anæsthetists where needed) as part of the domiciliary service should be made available in an emergency for a patient who has been admitted for her confinement to a private maternity home or for her baby during her stay in the maternity home, where medical considerations make it impossible for the patient to be removed to hospital "

The decision that regional boards shall administer the service (as some are already doing) means that all contracts for domiciliary consultations should be offered and made by these boards and each consultant should be in contract with only one regional board

Originally it was intended that all requests for a domiciliary consultation should be made through a hospital, "Experience suggests however, that the convenience of all concerned is best promoted by direct application by the family doctor to the practitioner he wishes to call in, and Regional Boards should organise their service accordingly " Furthermore, regional boards should seek the help of executive councils in informing general practitioners of the consultants available for consultation A special record and claim form for consultations is being introduced

---

Public Health

A HEALTH-SERVICES BUREAU

J A GILLET
M B Lpool, D P H
DEPUTY MEDICAL OFFICER OF HEALTH, ROTHERHAM

EVEN before the National Health Service Act came into operation in July, 1948, the scope of medical and social services was expanding, and this development was greatly hastened by the Act In Rotherham it was felt that the increasing complexity of these various services called for a new section of the health department to deal with inquiries concerning them The scheme envisaged by the medical officer of health and the health committee was for a section which would both meet the needs of people seeking information about such services and would also promote health education

The new section was opened on Sept 6, 1948, in the town hall, but this arrangement proved unsatisfactory because the offices could not be reached directly from the street Accordingly, the section was transferred last year to a building at the centre of the city These premises, which are on a corner site, have three main rooms One large front room, with a shop frontage on two sides, is furnished with chairs, tables, and display cabinets containing posters and pamphlets on health topics issued by the Central Council for Health Education and other agencies Official explanatory pamphlets and application forms for various benefits can also be had Behind this room is an office for private interviews, and also a room in which are stored wheel chairs, crutches, bed rests, bedpans, and other nursing and surgical appliances, which are available on loan in case of need, on return these are cleansed and sterilised Drums containing sterile equipment for domiciliary confinements are issued on request to midwives and general practitioners

The section is staffed by a health services information officer and one female assistant Excellent relations have been established with both the general public and the various agencies providing services locally, such as the hospital management committee, the executive council, and the Ministries of Food and National Insurance The public have come to realise that time can be saved, and frustration and needless journeys avoided, by calling at the bureau when they have problems connected with the health services, and use of the bureau has been encouraged by the willing coöperation of the local press, shopkeepers, business firms, and the transport undertaking in publishing its functions

From the outset the bureau has been busy, since September, 1948, over 11,000 inquiries have been received At first inquiries concerned mainly such simple matters as how to obtain glasses or dentures, or how to change doctors, but now the problems are usually less easy to answer Much time has been spent in explaining the method of completing forms of application for monetary and other benefits, these are often extremely perplexing to members of the public Every effort is made to deal with queries on the spot, giving definite and detailed advice, and avoiding fruitless reference of the inquirer from one office to another

Advantage has been taken of the window space to try to "sell" health to the public There have been displays on "coughs and sneezes," "vaccination and immunisation," "poliomyelitis," "clean food" "child welfare" "accidents in the home," and other topics These displays which are usually changed fortnightly have attracted requests from organisations such as the Women's Co Operative Guild, the Soroptimists, and youth clubs for speakers to talk on medical and medico-social subjects Film shows, talks, and discussions have been arranged by the health services information officer

In Rotherham the welfare services of the borough are not under the direction of the medical officer of health, but one of the large windows and part of the large front room, together with the services of the staff, have been placed at the disposal of the welfare committee These facilities are utilised for the display and sale of goods made by blind people, and there is also a boot repair service The venture has proved most successful as a means of disposing of goods made by the blind, and one section of the bureau is often able to help the other

That the bureau meets a real need has been proved not only by the number of inquiries but also by the thanks of satisfied "customers" There is the instance of the lady who embarrassed the health services information officer by publicly embracing him in token of her gratitude There is also the case of the middle aged man deaf as the result of the 1914–18 war, who had not realised that for over twenty years he had been entitled to a hearing aid from the Ministry of Pensions His gratitude after being supplied with one only three weeks after calling at the bureau, knew no bounds Finally, there are the repeated statements by callers that before visiting the bureau they had been referred from one office to another without success

Owing to the varied inquiries, the staff has to be fully conversant with the medical and social services, and they have also to be patient and above all sympathetic in their approach to inquirers The bureau, which began two and a half years ago as a tentative experiment, has become a permanent feature of the health department and of Rotherham

---

Statistics for London in 1950

A preliminary report by Sir Allen Daley, the county medical officer of health, shows that in 1950 the provisional birth rate in London was 15 0 per 1000 population, and the provisional death rate 11 3 The provisional rates for maternal mortality (0 56 per 1000 live and still births) and for infant mortality (25 per 1000 live births) were lower than any previously recorded in London The provisional neonatal mortality rate was 16 5 per 1000 live births

During the year diphtheria cases totalled only just over 100 with 3 deaths, compared with 7500 cases and 250 deaths in a pre-war year Now over 60 % of infants under the age of 5 are immunised, and at school ages the percentage reaches 75

In 1950 the number of tuberculosis notifications fell for the first time since the end of the late war, and the provisional death-rate has further declined to a new low record of 0 39 per 1000 population, compared with 0 52 in 1949

Influenza

In England and Wales the prevalence of influenza, judging by figures for the week ended Feb 3, is no longer increasing greatly Influenza deaths in the great towns during each of the six weeks from that ended Dec 30 to that ended Feb 3 numbered 102, 458, 890, 1099, 1239, and 1269 In the week ended Feb 3 the influenza death-rate in the great towns was 61 19 per million population. For the great towns grouped regionally the highest incidence of influenza deaths was in Wales, the incidence of deaths increased materially in the Eastern London and South-eastern and Southern regions and less decidedly in the East and West Ridings and the North Midland areas The death-rates by regions were as follows

Region	*Influenza deaths per million population*
Northern	14 52
East and West Ridings	61 27
North western	79 46
North Midland	81 96
Midland	88 81
Eastern	98 37
London and South-eastern	40 88
Southern	40 20
South western	70 45
Wales	105 52

The proportion of influenza deaths in patients over 55 years of age rose still further to 90 5%.

Weekly claims under the National Insurance Act have fallen substantially, new claims totalled 323,400 in the week ended Jan 30, compared with 370,500 374,400, and 395,600 in the three weeks up to Jan 23[1] Among a group of some 7500 London County Council employees sickness absenteeism of about 15% was recorded in the first half of January but in the latter half of that month it decreased to 12% and finally to 10%

Influenza Abroad —Strains from Turkey and also from Paris have been identified as A-prime Virus A-prime has also been found in Canada

Poliomyelitis

In England and Wales notifications of poliomyelitis during the week ended Feb 3 were as follows paralytic 21 (20), non-paralytic 11 (7), total 32 (27) Figures for the previous week are in parentheses

---

[1] Figures supplied by the Ministry of National Insurance See Registrar-General's Return for the week ended Feb 3 H.M Stationery Office Pp 20 6*d*

Medicine and the Law

Hospital Nationalisation

By an intriguing feat of forensic conclusion the Court of Appeal has decided in the Bland-Sutton case that two different appeals by parties interested are successful but that nevertheless the result remains the same as before

Lady Bland Sutton, who died eight years ago, bequeathed the residue of her estate on trust as an endowment for two objects (1) for a research scholarship, and (2) to pay the income to the Middlesex Hospital for the maintenance and benefit of the Bland-Sutton Institute of Pathology, then carried on in connection with the hospital. In a proviso to her will she directed that, if certain specified contingencies occurred, her trustees (the National Provincial Bank) were to transfer the endowment fund to the Royal College of Surgeons for the general purposes of the college These contingencies included the following events the hospital becoming nationalised or passing by any means into public ownership and the trustees becoming unable lawfully to apply the income to the objects named in the will. When the National Health Service came into operation on July 5, 1948, the bank naturally had to ascertain the effect upon the endowment fund Mr Justice Danckwerts held last July[1] that the contingencies had not happened There was, however, a further legal point for him to consider If the events specified in the proviso ever did happen, it might be at some date in the remote future That being so, the proviso might be invalid because it offended the technical rule of law against perpetuities, if so, the ultimate gift to the college would be void, though, if the college were in the lawyer s sense a charity, then it would escape the consequences of the rule

Mr Justice Danckwerts held that the Royal College of Surgeons was a charitable body and thus would have its chance to receive the fund some day, if and when the specified contingencies occurred But he also held that the contingencies had not happened yet, the Middlesex Hospital had not been nationalised and it had not passed into public ownership His decision did not satisfy two of the interested parties The college appealed against it on the ground that the operation of the National Health Service Act of 1946 did nationalise the hospital did pass it into public ownership and did make the bank unable lawfully to apply the income of the fund to the objects of the will On the other hand, the Middlesex Hospital Medical School, in a cross appeal, maintained that the prospective gift over to the college under the proviso was invalid

Three judges of the Court of Appeal have now unanimously decided that both sets of appellants are right, but that it makes no difference Mr Justice Danckwerts had held that the hospital was not nationalised because it did not wholly pass into public ownership the medical school became an independent corporate body which remained outside nationalisation The Court of Appeal holds that the hospital was nationalised in the sense which Lady Bland-Sutton contemplated Thus the contingency named in the proviso to her will has occurred. But the Court of Appeal also holds that the Royal College of Surgeons is not a charity, the judges finding themselves bound by a decision of 1899 Thus the gift over to the college is declared void There is nevertheless no intestacy Thus, though the Danckwerts judgment is upset and the judge's order of last July is discharged, the result is substantially the same as that which he then reached

The decision in 1899 (*In re the Royal College of Surgeons*) arose over the possible application of section 11 of the Customs and Inland Revenue Act, 1885, to the property of the college The Act exempted property "legally appropriated and applied for the promotion of education, literature science or the fine arts" The charters of the college and the relevant enactments having been exhaustively reviewed, and a judgment to the advantage of the Institution of Civil Engineers having been considered, Lord Justice Romer dwelt upon the dual nature of the objects and purposes of the college It certainly promoted education and science but it also promoted the interests of those practising surgery as a profession No exemption from the 1885 Act, therefore, could be claimed. No fresh material being offered to the Court of Appeal the 1899 decision has been followed Sir Raymond Evershed, Master of the Rolls, observed that the court could not, "without untenable refinements," come to the conclusion that the college's main or only purpose was of a public or charitable character and that any selfish professional purpose was only ancillary or subsidiary thereto

Relative Liability

In Fordyce *v* Doherty the jury has found an anæsthetist guilty of negligence and awarded £400 damages. The patient underwent an operation for duodenal ulcer, curare was injected to obtain muscular relaxation, it was alleged (though this was denied) that the arm was strapped above the head during the operation and that, on recovering consciousness, the patient found that he had lost the use of it The surgeon who conducted the operation was joined as defendant, but the jury found in his favour on the issue of negligence Mr Justice Cassels postponed judgment in order to hear legal argument There will doubtless be discussion of the relative liability of the North West Regional Hospital Board (in whose hospital at Highgate the operation was performed) and the defendant anæsthetist

---

[1] *Lancet* 1950 ii 155

Meanwhile it may be noted that, in cases arising out of the National Health Service, the Ministry is likely to shift liability, so far as it can, to the shoulders of members of hospital staffs This, at least, is the view expressed by the legal advisers of the Medical Protection Society in the annual report which that body issued last September Though the circumstances are not exactly parallel, it was the practice of the Treasury Solicitor, in years before the Crown Proceedings Act had enlarged Government departments' vulnerability to actions for damages, to stand behind the driver of Army lorries or Post Office mail vans when some plaintiff made a successful claim against an individual driver for injuries due to his negligence The Army Council and the Postmaster General were strictly not liable in law for the actions of their agents or servants, but the Crown paid the damages As with the nationalised industries, so with the Ministry's hospitals, there are legal problems to be worked out in the coming years One cannot blame the Ministry of Health (by whatever name it be called) for standing upon its legal rights to the possible detriment of hospital medical staffs, but the ministerial attitude should be noted In any event the medical practitioner should be aware that his own legal interests and prospective defence may be quite different from those of the hospital or the "employing authority"

Coroners' Rules

The Lord Chancellor and the Home Secretary have appointed a committee to make recommendations on the rules to be made under section 26 of the Coroners (Amendment) Act, 1926, relating to the procedure at coroners' inquests and at post mortem examinations and as to the forms to be prescribed under section 2[illegible] of that Act The chairman of the committee is Mr Justice Austin Jones The committee is ready to receive written evidence, which should be sent to Mr H W Wollaston, secretary to the committee, Home Office, London, S W 1, before the end of February

---

Parliament

Students' Examination of Hospital Patients

In the House of Commons on Feb 6 Mr Fred Longden called attention to the practice in teaching hospitals for patients to be examined intimately by groups of students, often against the natural inclination of the patients He was sure that the overwhelming number of consultants were all that could be wished, but he quoted a number of cases where he alleged women patients had been subjected to embarrassing and humiliating experiences That sort of thing, he said, ought to be stopped at the earliest moment Students should not merely be professionally taught and guided, they should be controlled in their treatment of men and women

Dr Charles Hill said that in his experience he had never seen or heard of unchaperoned examination such as Mr Longden had described Everyone must face the fact that if this country was to be happily served by efficient doctors, teaching on the diseased human body was essential Most patients were only too glad to coöperate, but a minority found it too difficult to bear, and he agreed that where people protested their objections should be respected

Mr Arthur Blenkinsop, parliamentary secretary to the Ministry of Health, pointed out that there had been no change in the principles of using patients in teaching hospitals to give students the necessary clinical experience The system had been used ever since our present methods of clinical teaching were evolved The only difference was that the teaching hospitals had perhaps more students under training than in the past Unless the principle of clinical examination of patients by students was accepted much of our medical training would be valueless and the public would be endangered He was convinced that it would be impracticable to get the consent of the patients in advance But he agreed that where a patient had expressed unwillingness to submit to an examination by students that objection should be dealt with sympathetically and understandingly, no pressure should be used The Ministry of Health would always be ready to investigate any cases in which it was suggested that any wrongful duress had taken place During the last year and a half only three or four cases had been reported to the Ministry He realised that there might be many cases where patients felt unhappy, but the majority appreciated the need for the procedure although they might not like it

QUESTION TIME

Hospital Registrars

Dr Reginald Bennett asked the Minister of Health what action he was taking to carry out the provisions of his circular about the dismissal of specialists under training from his hospitals, with what professional bodies he was discussing this action, and what results had yet accrued from such discussions —Mr H A Marquand replied I have received the proposals of some of the hospital boards and am awaiting others These will, where necessary, be discussed with representatives of the boards I am also having discussions, which are not yet complete, with the medical profession's joint committee

Infectious Diseases

Mr William Teeling asked the Minister if he would give instructions to all medical officers of health that they should release no information about dangerous infectious diseases without his approval—Mr Marquand replied No, Sir I think that the publication of information about local health conditions is very properly a matter for the local authority and not one in which I should normally intervene

Heroin

Mr A D Dodds Parker asked the Minister of Health what quantity of heroin was used in the United Kingdom now, compared with 1938, and to what causes he ascribed the difference —Mr Marquand replied The quantity in 1938 was 46 kg, and in 1949 it was 136 kg Diamorphine is widely used in this country as an ingredient for cough linctus A rise in consumption can therefore be attributed in part to medicinal use under the National Health Service

Diphtheria Statistics

Mr S P Viant asked the Minister how many of the cases of diphtheria notified in children under 15 were recorded as immunised or not immunised in 1945, 1946, and 1947, and if he would give similar information about the deaths from diphtheria recorded in those years —Mr Marquand replied:

INCIDENCE OF DIPHTHERIA IN CHILDREN UNDER 15

Year	Notifications	Notifications in which a full course of immunisation had been completed	Notifications not immunised	Deaths	Deaths in which a full course of immunisation had been completed	Deaths not immunised
1945	12 514	4431	8083	593	30	557
1946	7719	2723	4996	325	15	310
1947	3941	1287	2651	198	10	188

Staffing of Health Centres

Mr SOMERVILLE HASTINGS asked the Minister of Health what steps he proposed to take to provide for medical staffing when health centres had been built or acquired by local authorities and local doctors refused to make use of them.—Mr MARQUAND replied I am afraid I cannot generalise on this subject and the steps to be taken would clearly depend upon the circumstances of the particular case I should hope that agreement would normally be possible

B C G Vaccine

Mr S S AWBERY asked the Minister of Health if he would now permit general practitioners to inoculate with B C G vaccine and to give them discretionary powers in closed cases to send an inoculated child away from home —Mr MARQUAND replied Research into the use of B C G in this country is still continuing and I am advised that any general or indiscriminate distribution of the vaccine would not be prudent at present

Factory Doctors' Charges

Major W W HICKS BEACH asked the Minister of Labour whether he was aware that the proper charges of an appointed factory doctor under the Examining Surgeons Order, 1947, were not recoverable through the National Health Service, and if he would take steps to remedy this anomaly —Mr ANEURIN BEVAN replied These are charges for medical services which the employer is required to obtain under the Factories Acts for the purposes of his general responsibility for health and safety in his employment The National Health Service on the other hand, is provided for members of the community in a personal capacity and not to relieve employers of those obligations It is not anomalous, therefore that these charges are not recoverable from the National Health Service

Colonial Medical Service

Mr JOHN RANKIN asked the Secretary of State for the Colonies why the previous local D M S was asked to retire in view of the fact that the Tanganyika government was recruiting 20 doctors in South Africa owing to the shortage of doctors in the medical service, and what efforts were made to secure Asian doctors from East Africa or unemployed doctors in Malta —Mr JAMES GRIFFITHS replied The shortage of staff in the department at lower levels did not in the Governor's opinion justify retention in the service of the late director after he had qualified for retirement on pension under the relevant Tanganyika legislation No candidates were in fact recruited in South Africa but only 5 vacancies now exist for 2 of which candidates are in sight The Tanganyika government employ a number of Asian doctors A selection committee for recruitment to the Colonial Medical Service was set up in Malta in September 1950, and candidates recommended by it have already been selected for colonial appointments

Makerere College

Mr JOHN PARKER asked the Minister the length of the medical course at Makerere College, how many government scholarships were provided and whether leave of absence was granted for medical officers to complete the course to qualify as doctors —Mr GRIFFITHS replied The full diploma course lasts 7 years All of the 28 students at present taking the course receive government grants Selected African assistant medical officers are given leave of absence to acquire special postgraduate qualifications in the United Kingdom to assist them in their duties in East Africa

Mr PARKER What provision is made to enable African medical officers employed in Uganda to complete their training to qualify as doctors?—Mr GRIFFITHS Africans holding the Makerere diploma in medicine are already eligible to be licensed as medical practitioners on entering the Uganda government service as assistant medical officers and are accorded the title of doctor in East Africa. It is the aim of the college so to improve and adapt its diploma course that the General Medical Council will admit holders of a diploma to the British Register without further qualification such as is required by them at present

In answer to a further question Mr GRIFFITHS stated that 58 African assistant medical officers are employed by the government of Uganda of whom 9 are in charge of hospital units

In England Now

A Running Commentary by Peripatetic Correspondents

The Registrars were christened, and their training pre-determined
Their duties were important, though too numerous to state,
But like nylons, fully fashioned, through the National Health Service
They achieved a sudden glory This was 1948

They worked, they throve, they studied, they got married and had children
They got Memberships and Fellowships and everything was fine
They examined all the patients who attended all the hospitals
And wrote reports when ordered This was 1949

But the pound's devaluated and the dollar raised on high,
So the Treasury has suddenly turned thrifty
"We do not want to lose you, but we think you ought to go",
And they sacked the Senior Trainees 1950

Still the patients keep on coming with acute and chronic ills
Still the wards and clinics hustle and their work is never done
May it please you, Mr Marquand—won't you set the people free,
Won't you give us back our Registrars in 1951?

* * *

The increasing tendency towards specialisation revealed by medical Lifemen in these columns confirms my view that Medicinemanship (keeping one up on one's patients) is too restricted in scope to satisfy the really progressive Lifeman But in the wider, deeper, and perhaps tougher field of Wardsmanship (keeping one up on one's colleagues), and especially its late development Staffconferencemanship, much fine work is being done It is already clear that the budding consultant must choose between the Damn-Good-Doctor ploy and the Science-is-Movement gambit The latter is new and fashionable but a little too easy A pocketful of graph-paper and no stethoscope are the only essentials The requisite politely blank look to be assumed when asked for an opinion on a murmur or knee-jerk can be acquired in a few weeks if practised daily before a mirror A slide-rule, Fisher's *Design of Experiments*, and an equation or two pencilled on the back of an old kymograph tracing are excellent properties, as are a corked test-tube of soapy water in the waistcoat pocket and a tuft of guineapig fur on the lapel, a man I know got his junior clinical tutorship solely because he used an old piece of cardiac catheter to tie up his coat To establish oneself as a Damn-Good-Doctor is harder, but the rewards are greater A distinguished example is young Hartman-Heerwell, lately appointed to a fat consultantship in the Home Counties because the selection committee liked his statement that he "Didn't believe in all this damned new-fangled biochemistry" His often-repeated feat of inspecting the E C G of a puzzling case in the cardiac department in the basement, running up four flights of stairs and drifting nonchalantly into the ward "to have another look at that heart that's worrying us," just in time to make a confident diagnosis 'by good old-fashioned clinical methods" before the E C G report is telephoned to the ward through the official channels is one of the finest flowers of Wardsmanship Some day we must persuade him to tell us his methods in full

* * *

Before this series ends may I say a few words about the undergraduate branch of medical Lifemanship for the benefit of those who have not yet learnt the trick of carrying a stethoscope through the Metropolis with only the tips of the earpieces emerging from an outer pocket? The art of medical Studentmanship no doubt resembles that of any budding professional man with a position to maintain, but it has some features peculiar to itself For instance, there is the man in the opposite seat on the nine o'clock to Town who suddenly leans forward and asks in a low confidential but generally audible whisper "Why is it that a dose of salts acts at once, but cascara takes twelve hours ?" Any attempt at a straight answer would be to admit defeat But for the experienced Studentman there is an infallible counter ploy Don't be snared into leaning across to speak to the man but sit firmly back against the upholstery, express professional concern at the state of his bowels, and follow this up with a few brisk questions of as personal a nature as you can devise A certain winner for the trained man Far more serious situations will arise at home That off-hand question about what one has been doing today is a sinister offensive difficult to ward off because of its persistent though varied repetition Counter ploys are as follows

1 "Oh, nothing much" effective on occasions but leaves the Studentman in an unfavourable position if repeated too often

2 "Working' also occasionally effective but will not always stop your opponent s attack

3 "Attending a post mortem" the most effective ploy, especially if expanded, with full intestinal detail, at supper time

Another form of attack in the home is the Unreasonable Thirst for Information, hidden behind a casual question such as, 'Am I right in thinking that there's more than one form of pneumonia ?" The ploy here is the Reply of Unlimited Knowledge, in the case mentioned this would take the form of a speedy dismissal of lobar and bronchopneumonia in a few words followed by a learned dissertation on atypical and virus pneumonias If suitably varied, this defensive ploy should last the Studentman until the time comes for him to learn the more complicated art of Doctormanship

A no less important aspect of Studentmanship is that of getting one up on the Chief without actually dropping banana skins in the hospital corridor A fine example of this was played on a certain Registrar (who had certainly better remain anonymous) conducting a teaching round Seeing a student prodding rather disdainfully at a tumour with one hand the Registrar led off with "Are you, perchance, left-handed, Mr Whoosis ?" He was at once floored by the triumphant counter ploy 'I'm ambidextrous, sir" When the Registrar recounted the tale of his defeat later, the Chief enlightened him on the correct Triplecounter-ploy—obvious when one thinks of it "Then why not use both hands ?" But, of course, he is an acknowledged expert in Chiefmanship

* * *

The Ministry of Health Art Club (founded 1924) and Camera Club, the Hygeia (founded 1915), lately held a joint exhibition which should dispose for ever of any doubts hitherto cast on the sensitivity of the staff

Well displayed in the fine conference room were 80 paintings and drawings and 70 photographs There are many architects on the Ministry's staff, and their work was naturally prominent Among Mr Nicholson's several fine water-colours was a simple but effective study of the Undercroft, Westminster, which had quite a Russell Flint atmosphere Mr Deleuse, another architect, had several beautiful water-colour landscapes and a particularly good still life The doctors were not prominent among the exhibitors, but Dr W P Kennedy showed an oil and a water colour of scenes from the Lebanon, and two other landscapes There were some excellent oil paintings, and Miss Eileen Perrett's portrait of an old man was professional in its competence

The photographs were of first-class standard throughout, I have rarely seen a more beautiful collection The dozen shown by Sir Weldon Dalrymple Champneys, the club chairman, were worthy of an exhibition by themselves, and they were run a close second by Dr Harold Davis's pictures Among the rest I was particularly struck by the soft-focus studies by Mr Harrop

It was encouraging (to me) that there was not a single example of the atrocities now labelled "modern" Altogether a highly meritorious show

Letters to the Editor

METHONIUM COMPOUNDS IN HYPERTENSION

SIR,—Professor Smirk's letter in your last issue prompts brief comment lest it should be thought that experience in this country with the penta and hexamethonium compounds differs essentially from that in New Zealand In our experience these drugs will cause a marked fall of blood pressure in nearly all cases of hypertension However, some degree of tolerance tends to develop, and it is not always possible to maintain a satisfactory over all reduction in pressure without undue side effects, at least when the drug is given by mouth Far more clinical experience and detailed studies of the various hæmodynamic effects will be needed before the place of these compounds in the treatment of hypertension can be assessed Meanwhile encouraging results are being obtained in certain group of patients and a few tentative suggestions may be made

No patient should be submitted to surgical sympathectomy for hypertension until thorough trial with methonium has been made Likewise every patient with malignant hypertension should be so treated

When signs of left ventricular failure are manifest, life is rarely prolonged for more than a year or two Under such circumstances, an attempt to postpone further failure may reasonably be made by adding methonium to the other customary measures

Unless the patient is seen too late, and her condition is so serious as to prevent 48 hours' delay, every pregnant woman with toxæmia or severe hypertension should be given a chance to respond to methonium before pregnancy is terminated In favourable cases improvement will soon be manifest, and it should be possible to decide if it is safe to allow the pregnancy to continue The reward may well be a live child instead of a lost one If the pregnancy can be continued until a live birth is probable, the drug can be stopped a day or two before induction *No ill effects from these drugs on the fœtus or newborn infant have been observed* Finally it will be found that previously intractable symptoms attributable to the hypertension can often be relieved and may not return, at least for some time, after discontinuation of the drug

The time has probably not yet come for the long term treatment of relatively benign cases It is advisable first to obtain further experience in the more serious cases

Potential dangers have been emphasised [1] in order to discourage indiscriminate treatment Untoward events have been reported by a number of workers, and it is strongly recommended that the initial assessment should be made in hospital, where the patient can be under continual observation

RICHARD TURNER

Edinburgh

SIR,—The methonium compounds are now being used in a number of clinics, and growing experience is proving their efficacy in the reduction of hypertension

I have found hexamethonium bromide more effective than the pentamethonium compound My experience is that hexamethonium bromide lowers the blood pressure and relieves the hypertensive symptoms in most cases of essential and malignant hypertension, and in cases of chronic nephritis To observe the blood pressure chart of a hypertensive patient under the influence of hexamethonium bromide is one of the most dramatic experiences in modern clinical medicine The pressure fall precipitately within 24–48 hours, without toxic symptoms—a result that could not be achieved by any other method

---

[1] Turner R W D *Lancet* 1950 ii 353

Patients with chronic nephritis appear to respond equally well. One patient had marked albuminuria and was excreting 8 g of albumin per litre of urine After he had received the drug for eight days, this amount was reduced to 1 g per litre. This may, of course, be fortuitous, but the observation is worth following up in other cases Papillœdema and subjective symptoms such as headache, throbbing, and vertigo were relieved by the drug

One patient, who had undergone bilateral dorsolumbar sympathectomy for malignant hypertension without reduction of her blood pressure, responded promptly to the drug , in fact, she was the only patient in my series who developed toxic symptoms due to hypotension Her blood pressure fell from 260/150 to 110/60 mm Hg , it rose promptly on withdrawal of the drug for twenty four hours, and she ceased to complain of the toxic symptoms of faintness, blurring of vision, and nausea and vomiting caused by the temporary hypotension With this drug at our disposal it seems to me very doubtful whether patients should be advised to undergo sympathectomy for severe hypertension

Two patients with marked hypertension who had suffered minor episodes of cerebral thrombosis were given the drug with beneficial effects They did not develop any further cerebral thromboses although their blood pressures were greatly reduced

I have adopted the following scheme of dosage

Initially 50 mg is given every six hours by intramuscular injection no harmful effects have been seen from this dosage After two days one dose each day is increased to 100 mg reaching a dosage of 100 mg six hourly after a further four days These intramuscular injections usually have the desired hypotensive effect At this point one injection each day is replaced by an oral dose of 1 g this dose is increased by 1 g daily until 4 g a day is being taken by mouth (i e , after a further four days) This dosage is excessive for some patients who may be found to react satisfactorily to 1 g every twelve or eight hours so the daily maintenance dose by mouth may vary from 2 to 4 g

I have found that oral administration has a much less certain hypotensive effect than intramuscular injection The blood pressure fluctuates a good deal , but usually a patient with an initial blood pressure of 260/150 can be maintained at a blood pressure of 170/120 with oral administration

Treatment would certainly be more effective if the patient could give himself injections of the drug at home Many patients with diabetes mellitus are taught to inject insulin , but in the case of the methonium compounds 3–4 injections would be required each day It might be possible to develop a preparation of hexamethonium bromide for injection in a medium from which the drug would be absorbed slowly, giving a continuous effect , one depot injection each day might then suffice

The ten patients who have been treated here by this method are attending as outpatients Such patients must be kept under observation because the ultimate effect of lowering the blood pressure in cases of hypertension is still uncertain It has been reported that after three or four months' treatment the blood pressure has remained at a lower level, even when the drug was withdrawn , but this observation needs confirmation

Wanstead Hospital London E 11 ERIC FRANKEL

ÆTIOLOGY OF CHRONIC GASTRIC ULCER

SIR,—I read with great interest the article of Jan 27 by Mr Doran on the vascular component in the ætiology of chronic gastric ulcer, and his conclusions on the relation between mucosal filling and sympathetic action

It will be recalled that the observation by Barclay and Bentley [1] on the gastric arteriovenous anastomoses included not only the microscopic appearance of injected material but also the macroscopic colour changes of the gastric veins in response to stimulation during operation under general anæsthesia , in one case the saturation of a surface vein rose by 17% in three minutes Under high spinal analgesia the veins did not become pink on handling but retained the normal dark colour associated with unsaturated hæmoglobin

In Mr Doran's series it would be of considerable interest to know, first the height of the epidural block and hence the completeness of the sympathetic block, and secondly what colour changes were observed in the gastric veins during all the laparotomies But even with these data the observed results would not be quite comparable with those of Barclay and Bentley, who used intrathecal instead of epidural block as the method of sympathetic blockade

I have noticed that in some laparotomies under a combination of high epidural and light general anæsthesia the arteriovenous colour contrast is not so consistently marked as under spinal anæsthesia, although a profound vascular hypotension indicated a near total sympathetic block I do not know the explanation of this observation unless it is that the longer time required for complete development of epidural analgesia permits the transmission of a certain number of stimuli at the commencement of operation, and once opened the arteriovenous shunts remain open

Oxygen desaturation changes in gut blood vessels deserve further accurate study, and it is possible that quantitative observations by photo-electric [2] and spectroscopic oximetry or blood gas analysis under varying conditions of autonomic block will throw more light on the ætiology of chronic peptic ulceration

MASS RADIOGRAPHY

SIR,—If Dr Hoffstaedt (Feb 3) believes that the mass radiography method can be a potent force in a programme of tuberculosis control by the earlier diagnosis of active cases than is otherwise possible, then I am happy to declare an identity of view But I must criticise his aptitude for drawing theoretical conclusions from his figures in ignorance of practical considerations If it is really true that a unit in region 1 can only find 25,000 people to examine in a year because of the dispersion of the population, then I can only suggest that the unit should move to areas where the population is denser

The efficiency of a unit must be judged by its absolute results, not by " over all discovery rates " , and I have suggested two targets which should be regarded as minima (*a*) the discovery of 200 new active cases of tuberculosis per year for those who believe that tuberculosis case finding is the only justification for mass radiography , or (*b*) 46,000 examinations per year for those who recognise the benefits of the by products of mass miniature radiography unconnected with tuberculosis. In my opinion, a unit failing to reach either of these targets should carefully examine its methods and approach My own unit during 1950 made 54,965 examinations and discovered 263 active cases of tuberculosis I must maintain that 167 discoveries in a year compares ill with 200 and still more so with 263 I challenged Dr Hoffstaedt's criticism and conclusions about mass miniature radiography because he is apparently unaware of what can be done

Two final points First, $3^{1}/_{2}$ million examinations a year is the potential of the full 70 units already planned by the Ministry of Health Second, as every medical director knows, a thousand examinations can easily be made in two days, but not every working day is spent in taking miniature films The expression was used, of course to emphasise the smallness of the contact groups in terms of mass radiography work Dr Hoffstaedt wonders what my unit does during 150 working days for which he is unable to account I can tell him It does almost exactly twice as much work as he believes possible There lay the misconception on which his original paper was based

REGISTRARS

SIR,—One point which seems to have escaped your correspondents in writing about the registrars threatened with dismissal concerns the retiral age of consultants Some of them in the provinces go on for 2 or 3 years after they have turned 65, and where they happen to be members of regional boards it is difficult to believe that the advantages and disadvantages of this arrangement have been considered entirely on their merits When they were themselves registrars they were not kept kicking their heels by Peter Pans at the top of the queue If these old gentlemen want to work after 65, they should be like the retired admirals in the war who cheerfully became lieutenants, house surgeons are wanted in some places But they have no right to rob these deserving young men of their jobs and of experience I go round the country doing "locums" and see quite a lot of this pilfering by persisting in office It is very hard to protest locally, and almost impossible for a young man

Beckley Rye Sussex. C G LEAROYD

RESPONSE OF MEGALOBLASTIC ANÆMIAS TO PENICILLIN

SIR,—During the past year's work in Kenya on the anæmias of Africans, we were repeatedly struck by the response of some cases of megaloblastic anæmia to crystalline penicillin (sodium salt) G administered for intercurrent infections

On Nov 7, 1950, we examined a negress patient with megaloblastic anæmia The red cell count was 1 700,000 per c mm, hæmoglobin 5 0 g per 100 ml, and hæmatocrit 17%, and the sternal marrow contained megaloblasts and giant stab-cells there was complete histamine fast achlorhydria The patient had had several previous relapses of anæmia, and had been successfully treated with crude or refined liver Although she had no nervous symptoms the findings strongly suggested pernicious anæmia, which so far as we are aware has not been described in the Negro races of Africa

After five days observation, during which her reticulocytes were stable at 1 0–1 4%, she was put on to 400 000 units of crystalline penicillin daily for seven days By the sixth day of this treatment her reticulocytes had risen to 36%, and the red cell count to 2 420 000 per c mm, the hæmoglobin to 5 8 g per 100 ml, and the hæmatocrit to 24% The patient was discharged from hospital with a red cell count of 4,290,000 per c mm, hæmoglobin 12 0 g per 100 ml, and hæmatocrit 38% She visited us as an outpatient on Feb 3, 1951, when she had a red cell count of 4 900,000 per c mm hæmoglobin 13 5 g per 100 ml, and hæmatocrit 43%

The megaloblasts disappeared from the marrow very rapidly after the treatment and the giant stab-cells much more slowly, after treatment was started The only treatment given to this patient during the whole period was 2,800,000 units of penicillin

During the past month we have similarly treated with penicillin the megaloblastic anæmias of pregnancy, with the same striking results The response of both these types of megaloblastic anæmia to penicillin is in every way similar to the responses that we obtain to liver, folic acid, or vitamin B_{12} both in the Kenya cases and the Macedonian anæmias

The mechanism by which penicillin produces these responses is not at present clear, but we suggest that it may act in any or all of the following ways

(1) By changing the flora of the gut, or removing antagonists or competitors or other factors that may be interfering with the synthesis, absorption, or utilisation of hæmopoietic factors

(2) By interfering with bacterial metabolism in ways that may result in the release of hæmopoietic factors for the use of the body itself (i e, glutamic acid metabolism, which is known to be affected by penicillin)

(3) By affecting protein metabolism, and the synthesis of nucleoproteins from basic amino acids

(4) By virtue of its content of hæmopoietic factors such as vitamin B_{12}

A full report of these findings will be published in due course

A THERAPEUTIC EXPERIMENT IN PEPTIC ULCER

SIR,—I have read with interest Dr Stolte's article of Dec 23 Certainly therapeutic studies of placebos are of scientific interest However, Dr Stolte's conclusion that "any treatment for exacerbations of peptic ulcer has a chance of success" seems to me misleading.

In 1947 Gill[1] reported that of 20 patients treated with injections of a physiological saline solution very good results were obtained in 19 (95%) This is considerably better than the results obtained by Stolte yet Gill rightly concluded that ulcer patients should not be treated exclusively with a solution of common salt.

These two investigations prove that the psychical influence of the physician on the ulcer patient is of great importance To conclude from this, however, that any ulcer therapy has a purely psychological effect seems to me very far fetched, especially when we take into consideration such results as those obtained with 'Robaden'[2] in experiments on the rat, ulcers were unaffected by a placebo, whereas with robaden the number of ulcers was reduced

Robapharm Laboratories Ltd,
Basle

W ROSENBERG

DERMATITIS HERPETIFORMIS TREATED WITH CHLORAMPHENICOL

SIR,—This is a record of the first case of dermatitis herpetiformis to be treated in this hospital with chloramphenicol

The patient, a housewife, aged 52, had a spontaneous pneumothorax twenty five years ago, but no tuberculosis was found Five years ago she had an ovarian cyst removed. Her husband and one child, aged 19, are both alive and well.

The patient never had any skin trouble until twenty months ago, when her mouth became ulcerated, and thereafter she had repeated crops of vesicles on the palate, throat, cheeks, and base of the tongue, these readily formed shallow excoriations, causing considerable discomfort Intervals of freedom between attacks were brief

Six months ago, while using a plastic comb, she scratched her scalp, which bled slightly The few small abrasions did not heal, but gradually extended until the whole of the crown of her head was covered by offensive-smelling erosion and scab, against which penicillin and other ointments proved ineffective

Eleven weeks ago three fingers became septic, and one required incision Nine weeks ago a rash developed on the greater part of the body, with associated irritation Eight weeks ago (Oct 25) the patient was admitted to hospital

On admission the area over the vertex was uniformly raw and red, partly devoid of hair, with the surrounding hair matted by ointment and exudate There was pus under the proximal part of the red and thickened nail bed of one finger, paronychia of two other fingers, and pitting of several finger nails Shallow red erosions were found on the mucous membrane of the palate, buccal wall, and sublingual region, while many vesicles and bullæ of varying sizes, with erythematous bases, were present, mainly on the lower abdomen, but also on the rest of the trunk and on the limbs some had already ruptured and a few were secondarily infected. Heart, lungs, and other organs were normal, no adenopathy.

---

[1] Gill A. M. *Lancet* 1947, i 291

[2] Grandjean E *Rev méd Suisse rom.* 1948 7 447

Blood-count showed: hæmoglobin 90%, white cells 8800 per c.mm. (polymorphs 68%, lymphocytes 25%, monocytes 5%, and eosinophils 2%). Dermatitis herpetiformis was diagnosed.

For the first six weeks after admission the patient's condition remained unchanged. As vesicles and bullæ ruptured, dried up, and left deeply pigmented areas, so new vesicles and bullæ appeared. Local treatment was extremely painful and necessitated many hours of nursing care each day. Bleeding occurred from the bases of a number of the ruptured bullæ; there was slight axillary adenopathy; and the patient had mild intermittent pyrexia with a temperature up to 100·4°F. A full course of sulphapyridine for three weeks had no effect, and intramuscular injections of 'Anahæmin' 2 ml. on alternate days for two weeks had very little effect.

Blood-counts were as follows:

Nov. 8.—White cells 12 600 per c.mm. (polymorphs 63%, lymphocytes 17%, monocytes 11%, eosinophils 8%, basophils 1%).

Dec. 1.—White cells 15 200 per c.mm. (polymorphs 79%, lymphocytes 16%, monocytes 2%, eosinophils 3%).

Dec. 12.—White cells 10 900 per c.mm. (polymorphs 66%, lymphocytes 30%, eosinophils 4%).

Dec. 15.—Hæmoglobin 80% (11·8 g. per 100 ml.); white cells 10 300 per c.mm. (polymorphs 75%, lymphocytes 21%, monocytes 1%, eosinophils 3%).

Two weeks ago (Dec. 11) treatment was begun with chloramphenicol by mouth, 1 g. five times daily for six days, followed by 0·5 g. five times daily for two days and 0·25 g. five times daily for four days. Since then the patient's progress has steadily continued; old lesions have dried up and only a few very transient small vesicles have appeared in the region of both knees and wrists. Her profound depression was rapidly replaced by a very natural cheerfulness.

Since no report could be found of the effects of chloramphenicol in this condition, it was decided to use a large initial dosage in order to achieve the maximum success as quickly as possible. Although this is only an isolated case, the rapid and dramatic improvement in the patient's general and local condition warrant further trials of chloramphenicol in other cases of this most distressing condition.

I have to thank Dr W. J. O'Donovan for permission to publish this note.

Senior Registrar,
Dermatological Department.

SCIATICA AND LUMBAR PAIN

SIR,—I may have been lucky in my cases of "sciatica." Of nearly 150 treated in the past few years, only 6 had true sciatica. The remainder, although they had been previously diagnosed as sciatica and had not responded to treatment, were in fact cases of more or less severe gluteal fibrositis, giving rise to sciatic pain.

Obviously, if the gluteal muscles are spastic and painful on pressure, straight-leg movement will be impaired. Forward flexion of the body will put these affected muscles on the stretch, giving rise to sciatic pain. Sciatic pain can be produced in these patients by pressure over the myalgic spots in the gluteal muscles, and it is quite common to find the only spots causing this long-standing pain high up in the origin of the gluteus maximus in the superior curved line of the ilium, or even in the tensor fasciæ latæ.

I do not dispute that prolapse of an intervertebral disc will give rise to sciatica or lumbar pain; but my plea is for more conservative treatment, and in my experience daily treatment with the much-maligned adrenaline cream, massaged into the buttock on the affected side, paying special attention to the true myalgic spots, will usually provide relief. With this treatment it is not unusual for patients to become completely free from pain of long duration within one week.

London, W.1. LOUIS MOSS.

VACCINATION AGAINST SMALLPOX

SIR,—In the statements circulated to the press regarding the vaccinal condition of the cases of smallpox at Brighton, I noticed that nothing was said about the revaccination of the first fatal case. I have a letter from Dr Rutherford Cramb, medical officer of health for Brighton, in which he says that this patient had been vaccinated in infancy and in 1916. Dr Cramb adds that he does not think it "took." This point does not affect the actual fact that the man had been revaccinated in 1916. This should have been mentioned in any account of the vaccinal condition of the cases.

London, N.W.10. S. P. VIANT.

LEUCOCYTE-COUNTS IN THIOURACIL MEDICATION

SIR,—While several criticisms can be made of Dr Holliday's conclusion (Feb. 3) that leucocyte-counts cannot safely be omitted from the programme of routine supervision in patients undergoing thiouracil medication, one can be stated briefly.

His chief basis for the conclusion appears to be that the mortality-rate in 11 cases of agranulocytosis detected by leucocyte counts was 18% while in 15 cases detected by symptoms it was 46%. The difference in mortality-rates was therefore 28%. Twice the standard error of the difference is, however, about 35%, so the observed difference in mortality-rates is not statistically significant and might readily therefore be due to chance.

Royal Infirmary, Bradford. C. J. YOUNG.

RECENT HISTORY OF CORONARY DISEASE

SIR,—It seems possible that the surprising results reported by Dr Morris in his article of Jan. 6 and 13 might be explained on the hypothesis that arterial calcification is a process in part independent of atheroma (though atheroma provides a setting for it) and much more dependent on physiological ageing.

It is a commonplace that during the last forty years the period of active life has increased greatly. A man in group I or II of the Registrar-General's classification is expected to continue working until he is between 65 and 70 or even older—though of course less actively than when he was younger. It is common to find a solicitor, or executive, interested in gardening or some other physical activity even at 75, and I well remember being walked 27 miles over the Surrey hills by an old friend in his 67th year. Women have also changed; a woman of 70 may still run her home with the minimum of help, and be more independent than was her mother at 50. That is, all ageing processes, calcification among them, are being postponed.

To me this delay of senescence is the most remarkable biological phenomenon of our time. Men and women live to be older in years, but their activity changes little once they have passed the age of 50, and their senescence is correspondingly delayed; when it does arrive, it is shorter. I have been astonished by the number of my father's friends who decided to retire only when overtaken by some localised physical weakness at ages of 70, 75, or even more; they seem to me to be little older than the men of 55 whom I met before 1914.

This may be a local phenomenon. During the late war I met many students from Central Europe; they usually appeared much older than their English contemporaries, and one confided to me that the most surprising thing in England was the youth of the professors. When I told him their real age he was thunderstruck, for they were in fact rather older than the professors in his native country, who appeared far nearer senility.

In England this retardation of senescence appears to hold for groups I, II, and III of the Registrar-General's classification, it is less obvious in group IV, and much less evident in V It seems possible that factors such as nutrition and exposure to the elements may play a part, and it might therefore be worth comparing the incidence of coronary calcification in group V at ages 65–75 with groups I and II at ages of 80 and upwards Alternatively, the hypothesis that the change is due to the reduction in consumption of alcoholic beverages might be considered

GEORGE DISCOMBE

POLIOMYELITIS AND POLIOENCEPHALITIS WITH OPSOCLONIA FOLLOWING APPENDICECTOMY

SIR,—Dr Simpson suggests in his letter last week that the case I reported under the above title (Jan 27) might have been a case of *acute porphyria* He bases this suggestion on five features which he states are most unusual in poliomyelitis but typical of acute porphyria I should like to point out that three of these features (viz, "*considerable* delirium at the onset," "ascending flaccid paralysis," "pyrexia continuing for five to six weeks") were not reported by me A fourth feature (viz, "retention of urine at an early stage"), as I pointed out in my paper, has recently been reported "as being frequently encountered in the poliomyelitis patients both before the onset of paralysis and after"[1] My account of the examination of the cerebrospinal fluid contained only the abnormal features, *there were no red cells* present

There is, however, further circumstantial evidence to suggest that this was a case of poliomyelitis Two nurses who had come in contact with this case developed typical poliomyelitis within the period of incubation

London W 5

M D WARREN

NURSING INFECTIOUS DISEASES

SIR,—Dr Stanley Banks's letter of Feb 3 must have shocked many readers in its revealing statements on the nursing situation in some of the infectious diseases hospitals Most especially note should be made that "commonly a newly qualified general trained nurse has admitted that she has never had any practice in handling a baby, or in the principles of infant feeding" This becomes a double tragedy when such a nurse, assuming duty as a staff nurse, finds herself trying to cope with 25 infants and children, all under five years of age, acutely ill with whooping cough or measles

How is it that general trained nurses may not obtain any experience in an infants department, and how is it that, where a general hospital nursing school is inadequate in this respect, arrangements are not made with another hospital where an adequate infants department exists? Heads of nurses' training schools have a particular responsibility in this, no doubt arrangements are not always easy, but one feels that in some schools very limited attention may be given to this aspect of a nurse's training If it is true that general trained nurses are having to face unexpected and unacceptable urgent nursing responsibility for infants and young children then the sooner it be universally recognised that a S R C N is a very valuable person the better No field of nursing calls for higher skill or more precise techniques than does the handling of acutely sick infants Most certainly this is not the simple task which, even in high places, is sometimes assumed

Probably every general trained nurse should spend at least six months in a children's hospital or, if it is big enough, in the children's department of the general hospital The very small series of lectures in "children's diseases" now usually given to nurses in general training covers only a few general principles and momentarily lights up the trainee's interest in a fascinating subject

With regard to the dilemma which Dr Stanley Banks describes, of one student nurse and one ward orderly trying to cope with a ward full of ill children, is it not possible (even in an "infectious diseases hospital") for some of the mothers or near relations to go in with the child and look after him or her? In these hospitals, we are told, there are "hundreds" of empty beds why not make some of the empty wards into temporary residential accommodation for the nursing parents, and especially for young mothers? Such an arrangement, as well as helping the hospital, would satisfy all the more enlightened principles of parent child relationship in hospital The experience would be of educational value to the mothers, and it would give them a sense of satisfaction and perhaps enhanced confidence through having *contributed substantially to their child's recovery*

MUNCHAUSEN'S SYNDROME

SIR,—Munchausen's syndrome, of which Dr Asher wrote on Feb 10, must be fairly common, since most doctors working in general hospitals have met several cases, even allowing for some distension of the truth in their stories It would not be so important were beds not so short On the contrary, in better times these cases provided interesting exercises in diagnostic ingenuity

The present problem is how to avoid wasting beds on *them* Regional hospital boards and boards of governors should keep "Munchausen lists" from details supplied by their hospitals (some do this already). Should a doctor have suspicions, he could ring up the board But when should we become suspicious? Being doctors and not detectives, few of us are suspicious at once The main points are, I think, a slightly improbable story in a patient not sent in by a doctor A scarred abdominal wall makes it easier

A recent early case of Munchausen's syndrome walked *into the receiving room* coughing blood It started, he said, after a lorry crash in the north of Scotland, but he gave the name of the hospital in Scotland as the "Royal George" *We thought* this sounded more like a "pub," and soon confirmed that no such hospital existed A really difficult case may justify a search of the patient's clothing, in one case of mine this revealed evidence of a recent stay in prison at a time when the patient said he was in hospital

Dr Asher has done a service in providing a concise name for these cases I suggest that, when letting one of them take his own discharge, we tell him that we have found him to be suffering from Munchausen's syndrome Assuming that all casualty officers have read Dr Asher's excellent article, he might then, by *announcing his diagnosis* cut short his stay at his next place of call In spite of all this we must not forget that those with the Munchausen story, though tricksters, may yet be mentally, and sometimes physically, ill, and that we who are not can, as well as being clever, also be kind

Chase Farm Hospital,
Enfield Middlesex

C ALLAN BIRCH

SIR,—Our thanks are due to Dr Asher for his able description of Munchausen's Syndrome I should however, like to register a protest on behalf of the great Baron von Munchausen, who was far too wise a fool ever to have put himself in peril of having to undergo an abdominal operation, a plausible and likable rogue he would have been more likely to describe a new syndrome he had observed than one suffered by him

It is admittedly hard to improve on Dr Asher's name for the syndrome but, bearing in mind the amount of myth associated with these patients, their constant suffering, their lack of any fixed abode, their multiplicity of names and their apparent immortality, would it not be better known as the Ahasuerus[1] syndrome? The disadvantages are that a wrong ætiology and racial incidence may be inferred, but these objections also apply to the established eponym Œdipus, without having caused any confusion or international misunderstandings.

---

[1] Critchley M in the Medical Annual London 1948 p 256

It is surprising that Dr Asher has not discussed the treatment of this condition; yet it was a compatriot of von Münchausen, Till Eulenspiegel,[2] who emptied a hospital by explaining to the patients that he would make a universal remedy from the ashes of a sick man; to avoid any unnecessary waste, the sickest man would be burnt—the last man out when Eulenspiegel should call for those who had been cured to leave. A cure rate of 100% was recorded, but there were unfortunately numerous relapses after the healer had left the district.

Cheam, Surrey. Paul Wingate.

POTASSIUM DEFICIENCY IN IDIOPATHIC STEATORRHŒA

SIR,—The interesting case report last week by Dr Lubran and Dr McAllen illustrates the importance of potassium deficiency in the steatorrhœa syndrome. According to our experience in Birmingham hypokalæmia in varying degrees of severity may be expected at some time in at least 20% of patients with this disorder. From the reported case-records it seems likely that hypokalæmia is a common immediate cause of death. Of the 14 fatal cases in our series, at least 7 died in this way; but, with the recognition of the therapeutic importance of potassium, 3 cases have been resuscitated from clinical states previously considered irreversible. More moderate degrees of potassium deficiency may be detected following rapid weight-loss and in association with marked muscle weakness and diminished reflexes. It is also probable that the excessive lassitude experienced by many of these patients may result from a general deficiency of electrolytes and of intracellular potassium in particular.

Hypokalæmia is not necessarily associated with diarrhœa. Some patients have only 1–3 large bulky stools daily, loose but not watery. The fæcal excretion of potassium at such times is often 5–7 g daily. Even when the stools are normally formed and the patient is apparently well the daily excretion often remains between 2 and 4 g. It may well be that one of the beneficial effects of a diet rich in meat is the additional potassium provided.

In considering electrolyte excretion in the fæces, there is evidence that sodium and potassium are both reabsorbed and excreted from the intestinal lumen. Normally fæcal potassium is negligible and it is excessive only when the body's reserves of sodium are threatened, as in diarrhœas of varied ætiology. In such states it is probable not only that reabsorption may be diminished but also that potassium is actively excreted. The low blood-pressures commonly found in these cases may be an expression of the unstable electrolyte exchanges in steatorrhœa; of 100 cases of idiopathic steatorrhœa, 38 had at some time a systolic pressure of 95 mm Hg or less, irrespective of their clinical condition. Clinically the rapid gain in weight that may occur with the administration of potassium by mouth suggests that much of the potassium appearing in the fæces has been derived from the intracellular stores. For example, one patient, after losing 26 lb in eight months, regained this weight in eight weeks with oral potassium therapy.

A protest must be made therefore at the assumption by Lubran and McAllen that failure of potassium absorption is the cause of the hypokalæmia in their case. Failure of absorption has been the traditional explanation for deficiencies in the steatorrhœa syndrome, and flat tolerance curves have been regarded as proof positive of the theory. Evidence is accumulating that this simple hypothesis cannot be the complete explanation for many of the deficiencies encountered.

University of Birmingham. W. Trevor Cooke.

RESULTS OF SURGERY IN SCIATICA AND LOW BACK PAIN

SIR,—You have created a most unusual precedent in publishing a scientific contribution four months before it was read, acknowledging the fact quite bluntly in a footnote, and drawing special attention to the article in editorial comment. For some reason that is not easy to understand Mr Burns and Mr Young have thought it wise to submit to you material that was to have been presented to the International Society of Orthopædic Surgery and Traumatology next May, which would certainly have been the property of that society thereafter, and is probably their property now. It may be, of course, that in the circumstances the paper will not be read at all. Certainly most Colleges, Associations and Societies do not knowingly permit the reading of papers that have already been published long before.

London, W.1. Reginald Watson-Jones.

*** The authors of this paper were anxious that their findings should appear as soon as possible. When they sent it last October, they frankly stated that one of them was going to read a paper based on the same material at the congress of the International Society in May; but they clearly did not regard this paper as the property of the society, nor did we think we were infringing the society's rights by publishing it. In retrospect, however, we agree that we were not entitled, without the society's permission, to give a private contribution the cachet attached to the use of the society's name, and we regret that this permission was not asked.—Ed. L.

CURRENCY FOR TREATMENT ABROAD

SIR,—Since the war, shortages of foreign exchange have led to restrictions on the number of people going abroad for health reasons. Since 1947 applications for currency for patients to undergo medical or surgical treatment overseas have been considered by the Exchange Control Medical Advisory Committee, a panel of experienced consultants set up to advise the Treasury as to cases where currency should be allowed. Particulars are submitted through the patient's doctor direct to the committee, and each case is considered individually. Hitherto currency has been allowed in cases where the treatment offered a reasonable prospect of cure and where the treatment could not be had in the United Kingdom or in another part of the sterling area. During the last twelve months 93% of those who applied have been granted currency.

The committee is now pleased to be able to announce that it will be possible to relax the hitherto rigid rules under which applications for certain European countries have been dealt with. The Treasury have decided that as the result of the establishment of the European Payments Union, of which this country is a member, and of Britain's present favourable balance of payments position with the other members of the Union, it will be possible to release more currency for travel for health reasons in certain countries. In future, therefore, currency will be available for treatment in any of the countries listed below in cases of genuine illness, irrespective of whether treatment can be obtained in the sterling area. Chronic ill health will be considered on climatic or other reasonable grounds.

The countries are: Austria, Belgium, France, Greece, Italy, Liechtenstein, Luxemburg, the Netherlands, Portugal (including Madeira and the Azores), Spain

---

[1] Ahasuerus = Cartaphilus = Buttadeus = Lakedæmus = The Wandering Jew.

[2] Ein kurzweilig Lesen von Dyl Ulenspiegel. Strassburg, 1515.

(including the Canary Islands), Switzerland, Turkey, and the Western Zones of Germany.

The procedure for obtaining a permit enabling the patient to purchase currency remains the same: the patient's doctor is asked to send a statement of the medical condition together with his recommendation for treatment abroad to the Medical Secretary, Exchange Control Medical Advisory Committee, Tavistock House North, Tavistock Square, London, W C 1.

The rules for applications for currency for treatment in countries not listed above remain unchanged, except that where treatment is available in countries on the above list currency will not be provided for a country not on the list. In the case of Norway, Sweden, and Denmark, in view of special arrangements with these countries, currency for travel is freely available and it is no longer necessary to apply to the committee; applications should be submitted direct to a bank, who will advise on the details required.

The members of the committee are grateful for the help they have received from doctors. The need for currency restrictions of this kind is *not* relished by anyone, but we believe the system is working fairly and that it enables those who genuinely require to use currency for overseas treatment to receive permission with the minimum of formality.

Exchange Control Medical Advisory Committee, Tavistock House North, Tavistock Square, London W C 1

HARLEY WILLIAMS

PROSPECT OF WAR

SIR,—In this correspondence, the psychologists make great play with the concept that fear and provocation are in full swing in both international camps and dub these emotions as psychopathic. There is mental confusion here, due to the two different meanings of the word "fear." There is nothing psychopathic in fear, as denoting the realisation of danger. It is, in fact, an essential factor in survival. Nor is it psychopathic to take precautions against an envisaged danger. It would be better to use the word "panic" for irrational or disproportionate fear. Similarly it would be well to drop the use of the words provocation and paranoia to describe rational precautions against a clearly perceived danger. I see no panic fear in my countrymen in general, but it is plainly to be seen in some of our Professors.

Bridlington

P D H CHAPMAN

SIR,—I wonder whether your readers experience the same feeling of helplessness, tinged with exasperation, that I do when I read of the comings and goings of the politicians and diplomats? At the present time we have the sorry spectacle of the members of the United Nations acting as judges and counsel on their own disputes instead of submitting them to a *real* International Court of Justice, which men of good will throughout the world would honour and whose decisions they would be prepared to back up. Whilst there are good arguments against an International Police Force, I do not think it would be difficult to recruit the judges for the above court.

I am inclined to think that Dr Alex Comfort is right when he condemns these power-addicted men who are moved more by considerations of prestige than the desire for peace. I can see no hope for peace, unless the non-powerseekers combine all over the world (and I include the U S A and the U S S R) to insist that the politicians shall cooperate or compromise or else clear the way for others. Such an organisation could be called the Society for the Prevention of Cruelty to People. Alternatively, politicians should be debarred from holding office for longer than one year, and I can even foresee that conscription of reliable citizens as M P s, backed by a neutral civil service, may be found necessary.

There is no logical reason why the world's resources should not be assessed and exploited for the human race by an organisation parallel to the aforementioned international court. It has always amazed me that as a profession we struggle to save the lives of a few, whilst the politicians can direct the destruction of many.

Hull

L I HARDY

SIR,—Dr Lindsey Batten (Feb 10) gives a moving and sincere analysis of the terrible predicament which is looming up. Yet I would wish to enlarge and modify his picture.

I believe he is correct when he points out that there have been occasions in the past when men of good will simply *had* to fight a war. But the world situation today is unprecedented in the degree to which, for purposes of war and peace, this is "one world." No longer can any country's problems be *solved by war*, because of the wholesale destruction of man's productive powers which atomic war inevitably entails. The certain result of a world war in this atomic era would be the devastation of enormous areas: those who imagine that on the whole their particular areas and creeds would emerge the stronger would do well to reflect that the highly industrial west is far more vulnerable than the predominantly agrarian east, and that the breakdown of western civilisation would result in the appearance of Communism in *all* the devastated countries. These are cogent reasons for insisting on the abandonment of war as an instrument of policy—*and they are reasons which have never before existed.*

Kindliness, humanitarianism, ordinary productive work, and the fundamental satisfactions of freely expressing our individual talents in our social life—these are the values which we feel we must fight to preserve. But how to fight for them? Are they to be preserved by war which multiplies a thousandfold the situation in Nagasaki, where women are still aborting and giving birth to monsters five years after the explosion of one atomic bomb? By war which will place those doctors (who do not think hard and courageously here and now) in the company of the builders of the gas chambers, the war criminals, the released armament kings—which is already using our military personnel to teach the Germans how to fight under their former Nazi generals!

Are those the weapons which will enable our values to triumph? Some will answer: "No, but we must seek what allies we can." To say this is simply to state that "the end justifies the means"—forgetting that the end is destruction, and that the whole spirit of that remark is exactly what is held to be the menace of totalitarianism. Can we prevent murder by wholesale murdering?

No: the fight is on another level—that of all of us as reasonable individuals. We have to understand the insidious drift to war as well as the pathology of the open war seekers. We have to appreciate the limbo of dulled apathetic negativity into which our organs of written and spoken opinion have unwittingly led us. A month or two ago a well-known magazine featured coloured photographs taken from the aeroplanes which showered jellied petrol and other bombs upon Korean villages, and remarked upon the strange beauty of the scene . . . So far have we gone along the road to megalomania, paranoia, and perversion. Instances could be multiplied.

Politicians, caught in the complicated mesh of party politics, cannot think straightly.

Only ordinary decent people who are prepared to think, to face their consciences, and then to act—only these can catalyse our recovery from this drifting nightmare. There are already thousands of such people (some of them already active in the various peace movements). There must be hundreds of thousands as quickly as possible; once that order of magnitude is attained, there will be millions, and the first essential step to sanity will be taken with the repudiation of despair and destruction. *Peace will break out*. People's heads will lift, and the men of little stature in our governments will suddenly realise what a healthy democracy means.

Action of this kind will not be easy for each of us (how could it be in our present situation?)! We shall be attacked by those fearful that we favour unilateral disarmament in our present plight. To them it must be patiently explained that we do not propose any such thing, but rather the public and national repudiation of war as suicidal, and the careful examination of schemes for multilateral disarmament which are already in being.

As individual doctors, we can do a great deal to wake people up out of this nightmare—but there isn't much time. If we do not do our utmost, we shall (even though dead) bear a heavy responsibility as citizens of a country which could have turned the scales in favour of sanity at a most critical moment in the history of mankind.

I firmly believe that, as a matter of plain fact, this country *can* do it. I seek your help in the publication of this appeal.

London N.W.3 A. F. MOHUN

SIR,—We have been gratified to find, from private correspondence as well as from that published in THE LANCET, that so many colleagues share our point of view. Disagreement would appear to be based upon three premises: (1) that problems of peace and war are political and are not suitable subjects for a medical journal; (2) that the appeal was addressed to doctors in the wrong countries; and (3) that the danger of war derives solely from Russian aggression. In summary, our answers to these points are:

1. Doctors have a social responsibility as well as a personal one to their patients; they have an ethical tradition and an international allegiance. War is a symptom of mental ill health. Its results include wounds and disease. Doctors are, therefore, properly concerned in preventing it. An "epidemic of trauma" requires prophylactic treatment as much as any other epidemic.

2. We accept the suggestion that an appeal to doctors should be international in its scope. If citizens in other countries do not possess the same type of personal liberty which we have here, this does not absolve us from our own duty. The government and press of each country attribute the blame to others, but dare we assume that none of the responsibility is on our side? A war may start because either one of two parties wishes it or because both sides are stampeded into it by imaginary bogies. Each country should avoid decisions which can be misconstrued and should ensure that actions taken are determined only by real dangers.

3. It is not, in our opinion, true that the sole danger of war rests with Russian aggressiveness. Clearly it would not be possible to reach agreement here on what constitute real threats from the East; but the nature of propaganda makes it inherently likely that some, at least, of the publicised threats are exaggerated. Moreover, we believe, that some recent actions of the Western powers may not unreasonably be interpreted by others as being aggressive (whatever have been the intentions behind them). To specify, there is the advance beyond the 38th parallel in Korea, the occupation of Formosa, the decision to build a new German army, and the release of Krupp and other Nazi supporters.

Some, we recognise, will not accept these arguments; but supposing they are valid, what should we, as doctors do? Why, for instance, could we not take seriously Dr. Lambert's suggestion of a health race instead of an arms race? Much thought is needed before we are entitled to answer these questions. We therefore propose that a forum should be created on which a policy acceptable to a large proportion of the profession can be determined. We ask all who are interested to write to us so that they can be invited to take part in an exploratory meeting.

Obituary

CLARE OSWALD STALLYBRASS

M.D. Lond., M.D. Lpool, D.P.H.

Dr. C. O. Stallybrass was a member of the medical staff of the public-health department of the city and port of Liverpool for over thirty years. But he never allowed administration to take first place or to make him anything less than Locke's "whole, sound, round-about man." First and foremost he was a good doctor, and he was never cribbed and confined in his chosen field of public health. He loved medicine, and his work was done in the fertile atmosphere of that tradition.

He was born in 1881, son of the late Rev. W. O. Stallybrass, of Wallasey. From Birkenhead School he entered the University of Liverpool in 1898 and he took the Conjoint qualification in 1905, graduating M.B. Lond. with honours two years later. During his house-appointments at Liverpool Royal Infirmary and the Maternity Hospital he had already become interested in preventive medicine, and after a year as R.M.O. at Parkhill Fever Hospital he took his D.P.H. In 1909 he became assistant medical officer in the Liverpool port medical service. He started a campaign of rat-searching and rat-proofing of ships, and his methods have since been copied throughout the world. In 1900 he took his M.D. Lond. in State medicine.

[*Liverpool Daily Post*

During the 1914–18 war Stallybrass's career at Liverpool was interrupted by his service abroad as a sanitary officer in Macedonia and later as a specialist with the Serbian Army. For his work during an epidemic of typhus he was awarded the Order of St. Sava. On his return to Liverpool he was appointed an assistant medical officer to the city, and he became the epidemiologist of the strong team headed by E. W. Hope, which did so much to develop Liverpool's health service. Stallybrass's *Principles of Epidemiology*, which first appeared in 1931, revealed a mind of high quality. It was a departure from tradition, at least in this country, for it was an attempt by a doctor engaged in the day-to day work of a health department to bring within one compass the sum of contemporary epidemiological knowledge. With Hope, and, later with Prof. W. M. Frazer, he collaborated in the well known *Textbook of Public Health* and with Hope and Hanna he wrote *Industrial Hygiene and Medicine*. He was also lecturer in public health to the University of Liverpool for many years.

His medicine was warmed by humanity, and it must have been a delight as well as a challenge to him when, on the transfer of the poor-law hospitals to the local authorities in 1929, he was entrusted with their improvement and development. The task occupied him for years, continuing after his appointment as deputy M.O.H. in 1933. He carried out the work with sympathy and understanding, and his sense of medical tradition and his integrity dissolved many difficulties. During the war years the hospitals of the city withstood the strain magnificently, and looking back it is clear that the hospitals and the community are deeply in Stallybrass's debt

After he retired in 1948 he at last found time to revise his book on epidemiology He continued to take a lively interest in the learned societies of the city, over most of which, including the Medical Institution, he had presided His social conscience, whetted perhaps by his medical work, remained keen and he was an active member of the Personal Service Society and the Merseyside Marriage Guidance Council, and chairman of Liverpool Children's Hospitals management committee He also became a crusader for a bold and intensive attack on tuberculosis, which he urged in his popular lecture when the British Medical Association went to Liverpool last year for its annual meeting On this occasion Liverpool University gave him the honorary degree of M D He died at Clatterbridge Hospital on Jan 28

A colleague writes "Stallybrass had an engaging inability to say no to requests which touched the things in which his heart and mind were employed Lectures, articles, papers, letters—he found time and energy for all, without stint or loss of quality Immersed in his job, he was 'always busy about things belonging to his craft' My most abiding impression of him is perhaps his eagerness He was a tallish, thin man who strode along with a slight stoop forwards as though he wanted to see everything, and who—like an intense but not unwelcome Ancient Mariner—held you while he extracted your views on some problem, or your reaction to some idea or thesis of his When he was president of the Liverpool Medical Institution, there seemed to be no subject on which he could not say something to the point Outside medicine he had the same breadth and depth the Twenty Club found that he was equally at home in stamp collecting, archæology, music, literature, and mountaineering He maintained his eager alertness of mind and heart to the end A man of real quality, erudite, gentle, shrewd, kindly, humble, and unaggressive, he had the affectionate and admiring regard of his colleagues and many friends"

Dr Stallybrass married Irene, daughter of the late Canon Wetherhead, and they had two sons

Notes and News

DOCTOR AND PATIENT IN NORTHERN IRELAND

The Prime Minister's announcement, in October, 1949, of the British Government's intention to impose a charge of up to 1*s* for prescriptions was followed in Northern Ireland by reports from a number of urban practices that attendances in surgeries fell off sharply for several weeks apparently due to the belief that the charge would apply in Northern Ireland with immediate effect' This comment is made in the annual report[1] of the Northern Ireland General Health Services Board, which adds "Allowing for people deterred by genuine financial need, this fall in attendances may well indicate that a number of persons attend surgeries unnecessarily or for trivial reasons' The report says that unreasonable behaviour by patients seems to be increasing, and it cites the following examples threats to change to another doctor if a desired preparation is not prescribed, or if a certificate of incapacity for work is not supplied, irresponsible or thoughtless transfers to other doctors who are thought to be more generous in supplying prescriptions or certificates, failure in non urgent cases to adhere to the proper surgery hours, unnecessary and inconsiderate requests for visits made late in the day or at night, attempts to obtain emergency treatment at inconvenient hours from doctors other than the patient's own doctor when no real emergency exists in order to save the patient trouble, refusal to follow a doctor's instructions, and failure by patients who have complained against their doctor to appear at service committee investigations

TERMINATION OF PREGNANCY

Women who feel they have reasonable medical grounds for seeking the termination of pregnancy are often at a loss to know how to proceed The Abortion Law Reform Association wish to inform them of the proper course to pursue, and of the wider interpretation of the law for which recent decisions in the courts give precedence The proper course, they can now say is for the woman to consult her general practitioner and put before him the physical and mental grounds for her request If he regards the request as reasonable he should take a second opinion, and if this opinion is also in favour of terminating the pregnancy he should arrange for a competent surgeon to perform the operation. Judgments in the *Bourne* and *Bergmann Ferguson* cases give legal precedents to show that it is legal for a patient to ask her doctor for a termination of pregnancy, legal for the doctor to consider the request, and if he endorses it to get a second opinion, and legal for a surgeon to act on such opinions and to operate if these opinions are based on the preservation of the life or the health of the woman and are given in good faith

EMPLOYMENT FOR THE BLIND

"An employer has to make his business pay and no plan for placing blind people in industrial employment can hope to succeed on any other basis than that the blind worker can and should do a full week's work in return for a full week's wage

These words are the keynote of the report[2] of the Working Party set up by the Ministry of Labour who have been considering the facilities for employing blind people The report recognises blindness as a handicap, but as a handicap which can be, and often is, overcome There are about 87 000 registered blind persons in Great Britain, of whom 36 400 are within the normal working age range of 16 to 65 Of these about 11,000 are employed or training for employment. Among the remaining 25,000 of working age it is estimated that about 3000 would be capable of doing a job To give them their chance, the Working Party recommend the expansion of facilities for training and of services for finding suitable jobs Another way to help is they suggest, by breaking down prejudices against the employment of blind people in open industry, as distinct from sheltered workshops In the last 10 years at least 3000 blind people have been placed in normal jobs Light engineering shorthand and typing, telephone switchboards, and physiotherapy are all jobs at which they have proved their worth' The care of the blind, the Working Party hold, offers scope to both public and voluntary bodies, and the best results will probably be achieved by joint endeavour

BEHIND THE SCENES WITH SHAW

SECRETARIES of great men seldom remind us we may make ur lives sublime Those who see the prophet off duty, knit his mittens, endure his wilfulness, and smile to themselves at his foibles are inevitably more aware of the moss and stonecrop on the colossus than of the noble proportions best seen rom a distance Miss Blanche Patch[1] knew Shaw only as an ageing man, his wilfulness and foibles gaining on him as they must on even great ancients, and her stories of him, though kindly and well told, are mainly trivial. All the same they give some idea of the last quiet years, when, as she says, 'he was bored with us all and eager to be gone,'' when the brilliant talker wished to stop talking, and the only passion eft to him was work. Some things she tells us which no-one lse could, or perhaps would There is a charming section on his postbag, and a good deal, of rather specialised interest, about his diet His relations with his doctors were more reasonable than we have been led to suppose She admits he was attracted by osteopaths, faith healers, and any form of yoga but, on the other hand, when a doctor succeeded in convincing him that extract of pig's liver would cure his pernicious anæmia he placed himself in the doctor's hands and was entirely obedient On the whole, he listened equably to what his doctors had to say and then used his own judgment —which after all is what most doctors do themselves when they are ill.

A VERONESE FOR WESTMINSTER HOSPITAL?

FOR some months Paolo Veronese's *Resurrection* has been hanging over the altar in the Westminster Hospital chapel on loan from its present owners The governors of the hospital now have the opportunity to buy the picture for use in perpetuity in the chapel They will give up to half the cost from their discretionary funds if the remainder is subscribed. Donations should be sent to the Rev C Hildyard, 2, The Cloisters, Westminster Abbey, S W 1

University of Oxford

In a congregation held on Feb 6, the title of clinical lecturer in the university was conferred on the following

D A. Abernethy surgery, R. W Armstrong psychiatry A. D Carleton diseases of the skin A M. Cooke medicine D C Corry surgery, A Elliot Smith, surgery F G Hobson medicine F H Kemp radiology Sir William MacArthur tropical medicine, R G Macbeth diseases of the ear nose and throat P C Mallam medicine W Ritchie Russell neurology J C Scott surgery V Smallpeice diseases of children J A. Stallworthy obstetrics and gynæcology W Stoble, diseases of the chest (till Sept. 30 1954) W B Foley orthopædic surgery till Sept 30 1955)

University of Liverpool

At recent examinations for the diploma in tropical medicine and hygiene the following were successful

G G Bisley S-C Cheng J Devota Z Galls R T Kokade M. Postiglione S K. Rana P H E. Smith, B Teelock P A. Varasoonthrosoth.

Dr S K. Rana and Dr P H E Smith have been recommended for the Milne medal in tropical medicine and Dr P H. E Smith for the Warrington Yorke medal in tropical hygiene

Royal College of Surgeons of England

At a meeting of the council on Feb 8 with Sir Cecil Wakeley, the president in the chair, the Hallett prize for 1951 was awarded to Dr M W Reece

Diplomas of membership and diplomas in public health were awarded to those named in our report of the council of the Royal College of Physicians (*Lancet*, Feb. 3, 1951, p 297)

University of Malaya

Dr B H. Sheares has been appointed to the chair of midwifery and gynæcology

Born in 1907 in Singapore Dr Sheares qualified from King Edward VII College of Medicine Singapore He came to this country in 1947 on a Queen's fellowship for a year's postgraduate study during which he took the membership of the Royal College of Obstetricians and Gynæcologists Since his return to Singapore he has acted as head of the department of midwifery and gynæcology

Ross Institute of Tropical Hygiene

The annual course for laymen will be held at the institute, Keppel Street, London, W C 1, this year from Monday, July 23 to Friday, July 27 inclusive

Noah Morris Memorial Lecture

The first Noah Morris lecture will be given by Dr H. P Himsworth in the chemistry department of the University of Glasgow at 4.30 P.M on Wednesday, Feb 28 He will speak on Nutritional Factors in Liver Disease

General Medical Council Elections

Nominations for 2 Scottish medical representatives, 1 Irish representative, and 8 English representatives (including 1 living in Wales) should be sent to the council on or before Feb 28 Further particulars were given in our advertisement columns last week

British Association of Forensic Pathologists

This association has lately been formed with a membership, covering both England and Scotland, of people teaching forensic medicine and engaged in the practice of the subject The president is Sir Sydney Smith and the secretary is Dr Francis Camps, 79, Harley Street, London, W 1

Swiss Society of Internal Medicine

This society is holding its 19th annual meeting at Chur from June 1 to 3 The programme includes discussions on the pathology and treatment of nephritis and on the treatment of hypertension. Further particulars may be had from Prof Eric Martin, Policlinique Médicale Universitaire, Avenue du Mail 2, Geneva

Congress on Tuberculosis and Diseases of the Chest

A conference on this subject has been called during the Festival to show the work of men and women from Great Britain and to stimulate discussion It will be held in Oxford from July 16 to 21 and is sponsored by the Faculty of Radiologists, the Society of Thoracic Surgeons the Tuberculosis Society of Scotland the Society of Medical Officers of Health, the British Pædiatric Association, and the British Tuberculosis Association. The speakers will include Dr Marc Daniels and Dr Margaret Macpherson (Tuberculin Surveys), Dr A. Q Wells and Dr J Young (Vaccination with the Vole Bacillus), Dr Honor Smith and Prof R S Illingworth (Treatment of Tuberculous Meningitis), Dr J W Crofton Dr L E Houghton, and Dr Christopher Clayson (Present Position of Chemotherapy in Tuberculosis), Mr A. L d'Abreu and Dr J H. Hutchison (Bronchiectasis in Children) Dr J E Geddes (Rehabilitation and Resettlement), Mr R C Brock, Mr Price Thomas, Mr Oswald Tubbs, and Mr Holmes Sellors (Cardiac Surgery) Dr C M Fletcher (Pneumoconiosis) Dr F H. Young, Mr Ronald Edwards, and Mr V C Thompson (Pulmonary Resection for Tuberculosis) Further particulars may be had from the hon. secretary Dr Stephen Hall, 16 Grosvenor Place, London S W 1

Meeting of W.H O Executive Board

The meeting of this board, which opened at Geneva on Jan. 22 (see *Lancet*, Feb 3, 1951, p 297, *Ibid* Feb 10, p 357) ended on Feb 5 On Feb 1 the board agreed to recommend to the fourth World Health Assembly (to be held at Geneva in May) a budget for $7,677,000 in 1952 This is a compromise between the original proposal for a $8 380 000 budget put forward by Dr Brock Chisholm, the director-general, and the recommendations of the standing committee on administration and finance The board unanimously decided to allocate $50,000 worth of medical supplies to Turkey, to prevent epidemics among Turkish refugees from Bulgaria The Turkish government had declared that Turkey had been asked to admit within ten to twelve months 250,000 members of the Turkish minority living in Bulgaria About 60 000 immigrants had already arrived, and about 1000 refugees were crossing the frontier every day The board also agreed to recommend for approval by the World Health Assembly a four year plan for world health. This plan, which covers the period 1952–55, will provide a framework in which the detailed annual programmes of W.H O will be developed Major headings are strengthening of public health administrations expansion and improvement of training resources for health personnel of all categories and development of permanent world wide services and projects in coöperation with other agencies

The Darling foundation prize has been awarded to Prof H. E Shortt F.R.S, and Dr P C C Garnham for their joint work on the life-cycle of the malaria parasite in man and the monkey Prof Rene Sand, of Belgium, has been nominated for the Leon Bernard foundation prize.

Sickness Records

The Institute of Actuaries is holding a meeting in the hall of the Chartered Insurance Institute, 20, Aldermanbury, London, E C 2, on Monday, Feb 26, at 5 P M, when Mr F H Spratling, F I A, and Mr F J Lloyd, F I A, will speak on Personnel Statistics and Sickness absence Statistics

Horse Shoe Club

A meeting of this club, which was formed in 1932 to foster friendship and the exchange of medical research and clinical workers between America and Great Britain, will be held on Thursday, Feb 22, at 5 P M at 11, Chandos Street, London, W 1, Dr Geoffrey Bourne will be in the chair

Use of the Film in Medical Teaching

The Royal Society of Medicine and the Scientific Film Association are holding a demonstration and discussion on this subject on Monday, Feb 19, at 5 P M, at 1, Wimpole Street, London, W 1 The openers are Prof K J Franklin, Prof Robert Cruickshank, Dr P Cardew, Dr G Loxton, and Dr Brian Stanford

The Medical War Relief Fund

From September, 1949, to August, 1950, the distribution subcommittee of the fund made 26 awards, of which 23 were gifts and 3 were loans, amounting in all to over £3000 Most of the awards were for the education of children whose fathers had been killed in the war Help was also given to doctors who had suffered financial hardship as a direct result of the war and had found difficulty in re establishing themselves in practice Since the fund was started £19,000 has been voted in loans The fund has a balance of £15,000, and while it is expected that some of the beneficiaries, especially the younger children, will need continued help, the committee thinks it unnecessary for the time being to invite further contributions Mr F A Juler has succeeded Dr C L Batteson as honorary treasurer, and Dr A V Kelynack succeeds Dr A Macrae as honorary secretary

Courses for Health Workers from Overseas

The first of the British Council's courses for visitors from overseas this year will be on industrial medicine It is being planned with the help of Dr R E Lane, Nuffield professor in the department of occupational health in the University of Manchester, and will be held in Manchester and Birmingham from March 1 to 20 Another course, on port health and sanitary control, will be held from April 23 to May 4 under the direction of Dr M T Morgan in London and of Prof W M Frazer and Dr Edward Peirce in Liverpool There will also be a course on rehabilitation and resettlement of the disabled in London from Oct 15 to Nov 7 under the direction of Dr Harold Balme There are also to be courses on public health (London and Leeds, Sept 9–23) and water pollution (London and Birmingham, May 21–June 2) Medical publishing will be included in a course on book production and publishing (Edinburgh and London, April 5–20)

Travelling Fellowships

The Medical Research Council invite applications for the following travelling fellowships for 1951–52

Rockefeller Travelling Fellowships in Medicine —These fellowships are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad before taking up positions for higher teaching or research in the United Kingdom The stipend of fellowships tenable in the United States will be $2600 per annum for a single fellow, and $3000 for a married Fellow

Dorothy Temple Cross Research Fellowships in Tuberculosis —The object of the fellowships is to give opportunities for study or research to qualified British subjects of either sex intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms The fellowships will as a rule be awarded to candidates who wish to work outside the United Kingdom The stipend of fellowships will be £650 per annum for a single fellow and £900 for a married fellow

Alexander Pigott Wernher Travelling Fellowships and Grants —These awards are intended for qualified medical graduates with some experience of research in ophthalmology or otology In general fellowships will be offered for periods of up to a year for specific research purposes but grants may also be given for short term visits abroad to study methods of investigation and treatment Fellowships will provide for maintenance allowance and travelling expenses whereas grants will ordinarily cover travelling expenses only

Forms of application may be had from the secretary of the Council, 38, Old Queen Street, London, S W 1, and must be returned not later than May 1

Laboratory Animals Bureau

The annual congress of the bureau will be held at the University of Liverpool on Monday and Tuesday, April and 10 Sir Henry Cohen, F R C P, will open the congress, and Prof R E Glover will be in the chair The speakers will include Dr J W Howie Requests for invitations to the congress should be addressed to the Director, Laboratory Animals Bureau, Medical Research Council Laboratories, Holly Hill, London, N W 3

Lord Haden Guest has been appointed a Lord in waiting to the King

Prof Leslie Banks is making a lecture tour of Middle East countries, arranged by the British Council He is to visit Iraq Persia, Syria, and the Lebanon

Prof Henry Barcroft is visiting Pakistan, under British Council arrangements to study the development of preclinical medical training facilities

CORRIGENDUM —Lady Wood informs us that Dr George Cathcart, whose obituary we published on Jan 20 (p 17), took no formal part in the Queen's Hall Promenade Concerts beyond finding the cost of instituting the low French pitch

INFECTION AND IMMUNITY IN SMALLPOX*

A. W. DOWNIE
M.D., D.Sc. Aberd
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LIVERPOOL

THE recent outbreak of smallpox at Brighton is another reminder of the continuing hazard of the introduction of virulent smallpox into this country from parts of the world where it is endemic. In this lecture, however, I shall not, except incidentally, be concerned with the spread of infection in the community. I propose to consider the course of infection and development of immunity in the person who becomes ill as a result of infection with variola virus—i.e., the pathogenesis of smallpox. Any addition to our knowledge of this subject is likely to help in our understanding of the spread of infection in the community and its control.

The sequence of events which follow penetration of the tissues by micro-organisms, and the response of the host, have excited the interest of clinicians and pathologists for many years. Nevertheless, in many diseases, especially in virus infections, our knowledge is still very incomplete. In certain of the milder virus infections, such as measles, german measles and mumps, a good deal of information has recently been obtained by the study of experimentally induced infections in human volunteers. In smallpox this method of investigation obviously cannot be followed. But some information on the pathogenesis of smallpox may be obtained from the experimental pox diseases of animals and by the use of laboratory methods to supplement the clinical study of patients. In re-examining the matter a good deal of what I have to say will be speculative, and I shall in many places be posing old questions without providing fresh answers.

In earlier studies of smallpox the methods used for the detection of virus were (*a*) the microscopic examination of stained smears from the skin or mucous surfaces—a method extensively used by Paschen, and (*b*) the inoculation of animals—the cornea in the rabbit or the skin or mucous membranes of monkeys. These methods are not very sensitive. Inoculation on the chorio-allantois of the developing chick embryo serves to demonstrate the presence of variola virus and may be used to estimate its concentrations in tissues and fluids from smallpox patients. A few drops of smallpox vesicle fluid which has been diluted many thousand times with saline will still produce characteristic lesions on the membrane of the chick embryo.

THE INCUBATION PERIOD

The smallpox patient becomes ill from 9 to 15 days, commonly 12 days, after exposure to infection. What is happening in the body during this period? This question may be asked in many other infectious diseases and receive an equally unsatisfactory answer. Any hypothesis concerning the course of events in the incubation period of smallpox must take account of the accepted opinion among epidemiologists that at any rate most patients are not infective during the greater part of this period. Acting on this belief Friedemann (quoted by Kaiser 1949) in the Berlin epidemic of 1916–17 allowed several hundred smallpox contacts complete freedom to mix with other patients until the lapse of the normal incubation period. This procedure did not apparently promote the spread of the disease. Dixon (1948) during the smallpox outbreak in Tripolitania allowed contacts to carry on business activities between the 3rd and 9th day after exposure and never observed secondary cases arising from such contacts incubating the disease.

It is generally believed that the virus enters the body via the upper respiratory passages. It has been suggested that the virus first invades and grows in the mucosa of the respiratory tract and that there is great multiplication of virus in this tissue. From this focus virus enters the blood stream and infects the skin and other tissues at or just before the onset of illness. A primary lesion in the respiratory tract has not, however, been demonstrated. Councilman et al. (1904) in their study of post-mortem material from 54 cases found no evidence of such a primary lesion. The value of such negative findings is perhaps not great; pathological processes occurring during the clinical illness might obscure evidence of earlier changes, and many of Councilman's cases had been complicated by secondary bacterial invasion of the lungs. However, if a primary lesion occurs in the respiratory tract during the incubation period it is apparently not such as to render the patient infective by discharge of virus from the air-passages to the environment.

There are two forms of smallpox where the portal of entry of the virus is not the respiratory tract—namely, variola inoculata and congenitally acquired infections.

Variola Inoculata

As far as the available records show, the incubation period in variola inoculata was two or three days shorter than that of smallpox as ordinarily acquired. This difference might be due either to the greater size of the infecting dose of virus, to the more rapid entry of virus to the lymphatics or blood through the trauma of the inoculation, or to the more rapid growth of virus in the skin than in the respiratory mucosa, or to a combination of these factors. Involvement of the local lymphatic glands seems to have been a regular feature of variolation, but it seems unlikely that in this inoculated smallpox proliferation of virus in the mucous membrane of the upper respiratory passages was an essential feature of the incubation period.

Transmission of Smallpox Virus through the Placenta

In congenitally acquired infection the incubation period is often shorter than in the disease as naturally contracted. Marsden and Greenfield (1934), who have published the most complete data on this subject, found that in many of their cases the interval from the time of onset of illness in the mother to the time of appearance of the eruption in babies soon after birth was 9–12 days; if the babies were infected at the time of onset of the mothers' illness, the incubation period of the disease in these babies was 2 or 3 days less than in smallpox as usually acquired. As they observed, this congenitally acquired infection resembles variola inoculata in this respect. In a few of their cases and in those recorded by Dixon (1948), however, the incubation period was about that seen in the naturally acquired disease. Here, again, there is no question of infection by the respiratory route. The virus enters the fœtal circulation in the placenta, perhaps after infection of the cells separating maternal and fœtal blood, and in the incubation period it must multiply in the internal tissues of the fœtus. As some of the fœtal blood passes directly from the umbilical vein to the liver, Kupffer cells might well take up virus from the beginning of the incubation period.

In naturally acquired smallpox, then, the incubation period is 2 or 3 days longer than in variola inoculata and in the congenitally acquired infection. These 2 or 3 days might represent the interval which occurs, in the common form of the disease, between the implantation of virus on the mucosa of the respiratory tract and its spread by the blood stream to those other tissues where multiplication is to continue.

That viræmia occurs in all cases early in the disease there can be no doubt.

GROWTH OF VIRUS IN THE SKIN AND DEVELOPMENT OF THE FOCAL ERUPTION

Although focal lesions are clinically obvious only on the skin and mucous membranes, post mortem studies have shown that specific lesions, less numerous than on the skin, may occur in internal organs. The virus shows a special preference for skin epithelium, although there is histological evidence of infection of endothelial cells of capillaries in the dermis and this presumably precedes the infection of the malpighian layer of the epidermis. By the time macules appear in the skin on the 3rd or 4th day of the disease there has been extensive multiplication of virus in the epithelial cells, and stained smears from scrapings of the papular lesions show very numerous virus particles. Histological examination of the skin from patients who die early confirms the impression obtained from examination of smears. There must be at this stage a tremendous amount of virus in the skin of the patient who is to develop a confluent rash.

In the average case virus is not present on the surface of the skin at this stage owing to the impervious nature of its superficial layers. In the mucous membrane of the mouth and pharynx, however, there is no such covering, and, at the time macules are appearing in the skin, lesions in these mucous membranes are breaking down and discharging virus on the surface. It is from the expulsion of droplets containing this virus that the patient becomes infective about the 3rd day. The few attempts made to isolate virus from the throat before the 3rd day of illness by egg inoculation have been unsuccessful. Ricketts and Byles (1908, p. 59) state that "the disease is seldom infectious before the outcrop of the focal rash" an opinion with which most clinicians and epidemiologists with experience of smallpox agree. If smallpox were, like influenza, always highly infectious from the onset, when clinical diagnosis is impossible, control of outbreaks by the isolation of cases and vaccination of contacts would be very difficult.

DEVELOPMENT OF IMMUNITY

The fall in temperature and improvement in the patient's condition, which becomes evident as the skin eruption appears, suggest that immunity to the virus or its products develops about the 4th to 6th day of illness. This is supported by observations to be mentioned presently. But antibody formation—an essential part of the immune response—which often occurs at this time does not, in most cases, prevent the progressive evolution of the skin eruptions through vesiculation and pustulation. By the time the vesicular stage is reached, or even earlier, probably all the epithelial cells of the skin which are to be infected already harbour virus, and within the cells the virus is protected from the action of antibody. The subsequent development of pustulation is part of the inflammatory reaction to the necrosis of epithelial cells previously infected by virus. The secondary fever, when it occurs, is probably caused, as Ricketts suggests, by the absorption of toxic products of tissue breakdown, and is related to the extent of skin involved.

I mentioned that there is other evidence of the development of immunity about the 5th day of disease. It was shown by Ricketts and Byles (1908), and subsequently confirmed by Marsden (1948), that a decreasing number of patients may be successfully vaccinated in the early days of illness and very few after the 1st or 2nd day of the focal eruption. Fig. 2 has been prepared from their data. It might be suggested that the failure of vaccination was due to an interference effect—to a refractory state of the skin in consequence of previous infection of this tissue with variola virus. It seems more likely to be due to the presence of specific antibody, which can be demonstrated in the blood after the first few days of illness. It must be kept in mind that an immunity response by the antibody forming tissues may take place a short time before excess antibody is demonstrable in the blood by laboratory methods.

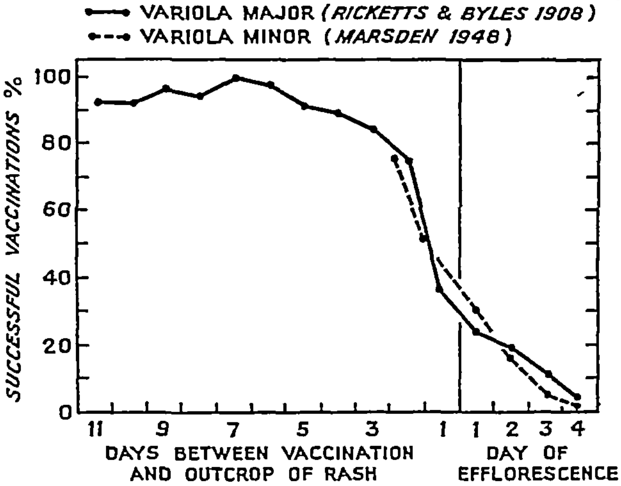

Fig. 2.

Antibody in serum may be estimated by various techniques—by complement fixation, by tests for inhibition of virus hæmagglutinin, or by various types of neutralisation tests against variola or vaccinia virus. Only the third kind of test measures the power of serum to inhibit the infectivity of the virus, but the first two serve to indicate an antibody response to virus antigen.

Collier et al. (1950) tested sera from 800 smallpox patients in Java for vaccinial antihæmagglutinin. Their findings showed that this antibody was present in significant amount between the 2nd and 5th day of illness, increased up to the 9th day, and remained at a high level thereafter. Our own observations on a much smaller number of sera gave similar results (McCarthy and Downie, to be published). Estimation of antibody by complement fixation gave results which paralleled those obtained by the test for antihæmagglutinins. Estimation of neutralising antibody in our series was made by inoculating mixtures of sera and variola virus on the chorio allantois. The extent of the reduction of the pock-count gave an estimate of the neutralising potency of the sera. Many of the patients whose sera we have examined had been previously vaccinated, most of them years before. In order to assess the significance of our results in smallpox cases, therefore, we have to take account of the duration of antibody response following vaccination. This is discussed later, but in considering the possible pre-existing antibody in the smallpox cases who had been vaccinated, we can say that complement fixing antibody, if present at all after vaccination, disappears within a few months and that antihæmagglutinin is usually not to be found after one or two years. Neutralising antibody may be detectable for many years.

In the sera from smallpox cases complement fixing antibody and antihæmagglutinin were present in high titre toward the end of the first week from the onset of illness. Neutralising antibody had also appeared or increased in amount at this time. We have made few observations on sera from toxic cases, but Collier et al. (1950) note that patients who die in the early eruptive stage show a poor antibody response as estimated by antihæmagglutinin titrations. Some of their patients who died towards the end of the 2nd week or later showed a high antihæmagglutinin titre. Such an occurrence is not unknown in other diseases where death may result

Evidence from Infection in Animals

In the absence of direct evidence from observations in smallpox, as to the site of multiplication of the virus in the incubation period, we may turn to Fenner's work on mousepox which provides useful suggestions (Fenner 1948a and b) This work was summarised by Professor Burnet not many months ago (Burnet 1950) In mouse pox, infection takes place through the skin After an incubation period of 7–8 days a local lesion appears, followed after 2 more days, in mice which do not die of the acute disease, by a generalised skin rash which in its evolution has some resemblance to the eruption of small pox Fenner infected batches of mice by intradermal inoculation and followed the spread of virus by titrating the virus content of various organs of animals killed at daily intervals afterwards He concluded that virus from the skin passed within a few hours to the local lymphatic glands, where it proceeded to proliferate Within a day or two, small amounts of virus passed into the blood stream, from which it was removed by phagocytic cells lining sinusoids in the spleen, liver, and presumably other tissues such as bone marrow In these organs there was further multiplication followed by an overflow of virus into the blood, at this time the skin was infected and the rash appeared 2 or 3 days later As Fenner noted, the sequence of events in the incubation period was similar to that observed in mouse typhoid by Ørskov and his colleagues (1928, 1930)

In Fenner's papers I have found no mention of systematic examination of the lungs for virus during the incubation period We know that intravenously injected bacteria and inanimate particulate material is partly removed from the circulation in the alveolar walls of the lung In Fenner's mice it seems possible that virus was removed in a similar manner during the initial viræmia, as well as during subsequent passage of the blood through liver and spleen In rabbitpox, which is clearly more akin to smallpox, the virus localises and produces lesions in the lungs with great regularity (Greene 1934) And after intradermal injection of some strains of vaccinia virus into rabbits, pulmonary lesions are commonly seen (Douglas et al 1929, Pearce et al 1936) These observations seem to suggest that if there is an initial viræmia early in the incubation period in smallpox, virus might be removed from the blood by phagocytic cells in the pulmonary capillaries and multiply there as well as in phagocytic cells in liver, spleen, and other tissues during the incubation period

Where then is the initial site of penetration and multiplication of virus in smallpox naturally acquired ? We simply do not know It seems most unlikely that the virus multiplies sufficiently in the epithelial layers of the mucous membrane at the site of initial lodgement to give rise directly to the viræmia which ushers in the clinical illness It is difficult to believe that such local proliferation of virus could go on for so long and the patient not be infective for others Might the initial infection of the tissues be lower down in the respiratory tract—for example, in the smaller bronchi or bronchioles, from which dissemination to the environment might less readily occur ? Another possibility is that the virus might pass through the mucous membrane without infecting the epithelial cells and be carried to the lymphatic glands to multiply there There is no evidence in favour of this idea, and later, at the onset of illness, the virus distributed by the blood stream infects the epithelial cells in the upper respiratory tract readily enough.

In any event, whether some degree of proliferation of virus takes place in epithelial cells at the site of entry or not, it seems likely that, during the incubation period, infection progresses in the manner suggested by Fenner's work The lymphatic glands draining the site of entry become infected early, and after a day or two virus is liberated from or within infected cells in these glands and passes to the blood stream to give a primary and *possibly transient viræmia* The virus is quickly removed from the circulation by phagocytic cells lining the sinusoids of the liver and sinuses in the spleen and bone marrow, and perhaps by phagocytic cells in the lung capillaries Only after a further period of multiplication and progressive infection of these cells does overflow of virus take place, giving the secondary and more intense viræmia at or just before the onset of illness. The complete disappearance of the capillary walls in the liver, which Councilman and his colleagues noted in rapidly fatal cases, may well have been the result of the extensive infection of the Kupffer cells during the incubation period

There is no generally accepted explanation for the localisation of virus in the skin during the secondary viræmia The liability to intermittent slowing of the circulation in the skin capillaries, and the probability that virus is within cells or associated with cell fragments may be important factors The concentration of the eruption at pressure points is compatible with the idea that capillary stasis may determine skin localisation (Ricketts and Byles 1908)

THE ONSET OF ILLNESS

The overflow of virus into the blood stream to give the secondary viræmia is believed to coincide with the onset of illness This viræmia leads to widespread infection of the skin, mucous membranes, and other tissues, although lesions do not become apparent in the skin for a further 2 or 3 days There may be viræmia shortly before the onset of illness, but on this point we have no direct evidence If the time of appearance and development of skin lesions in monkeys and rabbits after intravenous injection of variola virus and vaccinia virus respectively, are any guide as to what happens in the skin of the smallpox patient, the viræmia occurs just about the onset of illness and not before The observations of Dixon on infection contracted in utero are compatible with this It seems likely that, excep in severe cases, the period of viræmia may be limited t a day or two or even to a few hours Kyrle and Morawet (1915) claimed to have demonstrated the infectivity o blood, by intravenous inoculation of monkeys, throughou the clinical illness until the skin lesions were drying up These findings have not been confirmed by our ow observations (Downie et al 1950), or by those o MacCallum et al (1950), using the chorio allantoic metho

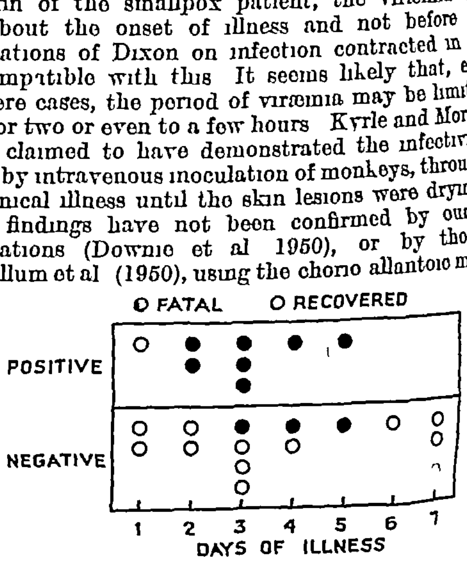

Fig 1

to detect virus Fig 1 summarises the combined fin ings of the two laboratories up to the end of Decemb 1950 It will be noted that, with one exception, positi results were obtained only in patients who ultimate died of their disease and in whom the viræmia mig be expected to be greater in degree and more prolonge The method permits of the examination of only sm samples of blood, and more positive results might ha been obtained if larger volumes of blood had be examined or if specimens had been obtained earlier the illness In a few instances concentration of spe mens by high speed centrifugation of lysed blood-ce was tried, but such specimens gave negative resu

That viræmia occurs in all cases early in the disease here can be no doubt

GROWTH OF VIRUS IN THE SKIN AND DEVELOPMENT OF THE FOCAL ERUPTION

Although focal lesions are clinically obvious only on the skin and mucous membranes, post-mortem studies have shown that specific lesions, less numerous than on the skin, may occur in internal organs The virus shows a special preference for skin epithelium, although there is histological evidence of infection of endothelial cells of capillaries in the dermis and this presumably precedes the infection of the malpighian layer of the epidermis By the time macules appear in the skin on the 3rd or 4th day of the disease there has been extensive multiplication of virus in the epithelial cells, and stained smears from scrapings of the papular lesions show very numerous virus particles Histological examination of the skin from patients who die early confirms the impression obtained from examination of smears There must be at this stage a tremendous amount of virus in the skin of the patient who is to develop a confluent rash

In the average case virus is not present on the surface of the skin at this stage owing to the impervious nature of its superficial layers In the mucous membrane of the mouth and pharynx, however, there is no such covering, and, at the time macules are appearing in the skin, lesions in these mucous membranes are breaking down and discharging virus on the surface It is from the expulsion of droplets containing this virus that the patient becomes infective about the 3rd day The few attempts made to isolate virus from the throat before the 3rd day of illness by egg inoculation have been unsuccessful Ricketts and Byles (1908, p 59) state that "the disease is seldom infectious before the outcrop of the focal rash" an opinion with which most clinicians and epidemiologists with experience of smallpox agree If smallpox were, like influenza, always highly infectious from the onset, when clinical diagnosis is impossible, control of outbreaks by the isolation of cases and vaccination of contacts would be very difficult.

DEVELOPMENT OF IMMUNITY

The fall in temperature and improvement in the patient's condition, which becomes evident as the skin eruption appears, suggest that immunity to the virus or its products develops about the 4th to 6th day of illness This is supported by observations to be mentioned presently But antibody formation—an essential part of the immune response—which often occurs at this time does not, in most cases, prevent the progressive evolution of the skin eruptions through vesiculation and pustulation By the time the vesicular stage is reached, or even earlier, probably all the epithelial cells of the skin which are to be infected already harbour virus, and within the cells the virus is protected from the action of antibody The subsequent development of pustulation is part of the inflammatory reaction to the necrosis of epithelial cells previously infected by virus The secondary fever, when it occurs is probably caused, as Ricketts suggests, by the absorption of toxic products of tissue breakdown, and is related to the extent of skin involved

I mentioned that there is other evidence of the development of immunity about the 5th day of disease It was shown by Ricketts and Byles (1908), and subsequently confirmed by Marsden (1948), that a decreasing number of patients may be successfully vaccinated in the early days of illness and very few after the 1st or 2nd day of the focal eruption Fig 2 has been prepared from their data It might be suggested that the failure of vaccination was due to an interference effect—to a refractory state of the skin in consequence of previous infection of this tissue with variola virus It seems more likely to be due to the presence of specific antibody, which can be demonstrated in the blood after the first few days of illness It must be kept in mind that an immunity response by the antibody-forming tissues may take place a short time before excess antibody is demonstrable in the blood by laboratory methods

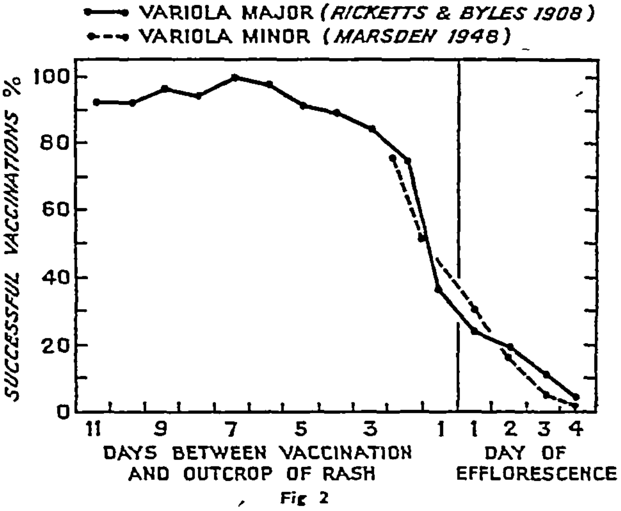

Fig 2

Antibody in serum may be estimated by various techniques—by complement fixation, by tests for inhibition of virus hæmagglutinin, or by various types of neutralisation tests against variola or vaccinia virus. Only the third kind of test measures the power of serum to inhibit the infectivity of the virus, but the first two serve to indicate an antibody response to virus antigen

Collier et al (1950) tested sera from 800 smallpox patients in Java for vaccinial antihæmagglutinin Their findings showed that this antibody was present in significant amount between the 2nd and 5th day of illness, increased up to the 9th day, and remained at a high level thereafter Our own observations on a much smaller number of sera gave similar results (McCarthy and Downie, to be published) Estimation of antibody by complement fixation gave results which paralleled those obtained by the test for antihæmagglutinins Estimation of *neutralising antibody* in our series was made by inoculating mixtures of sera and variola virus on the chorio allantois The extent of the reduction of the pock-count gave an estimate of the neutralising potency of the sera Many of the patients whose sera we have examined had been previously vaccinated, most of them years before In order to assess the significance of our results in smallpox cases, therefore, we have to take account of the duration of antibody response following vaccination This is discussed later, but in considering the possible pre-existing antibody in the smallpox cases who had been vaccinated, we can say that complement fixing antibody, if present at all after vaccination, disappears within a few months and that antihæmagglutinin is usually not to be found after one or two years Neutralising antibody may be detectable for many years

In the sera from smallpox cases complement fixing antibody and antihæmagglutinin were present in high titre toward the end of the first week from the onset of illness Neutralising antibody had also appeared or increased in amount at this time We have made few observations on sera from toxic cases, but Collier et al (1950) note that patients who die in the early eruptive stage show a poor antibody response as estimated by antihæmagglutinin titrations Some of their patients who died towards the end of the 2nd week or later showed a high antihæmagglutinin titre Such an occurrence is not unknown in other diseases where death may result from the late effects of earlier damage to vital tissues or from secondary infection

The application of laboratory methods for the measurement of the immune response has served to confirm the views, based on clinical experience, of such authorities as Ricketts and Byles It seems that the speed of the immune response determines the severity of the disease and that the outcome will be decided by what happens in the body in the first few days of illness In persons (usually well protected by vaccination) who suffer from *variola sine eruptione* the rapid formation of antibody engendered by the stimulus of infection does not prevent the liberation of virus from cells where it has been multiplying during the incubation period That viræmia occurs in such cases is supported by the observation of Bancroft (1904) He mentions, without giving details, a pregnant woman who, after contact, had only a vague illness with some headache but later gave birth to a baby who developed a typical smallpox eruption 2 days after birth In these *sine eruptione* cases antibody probably combines with the liberated virus and prevents infection of the skin epithelium If the response is less effective some of the virus exposed to antibody in the blood stream early in the disease may be neutralised, thus diminishing the number of focal lesions, or the antibody may prevent progressive infection of skin epithelium before the eruption becomes clinically apparent, thus preventing the full development of the skin lesions and so leading to modification of the rash

PERSISTENCE OF ANTIBODY

As second attacks of smallpox are uncommon it seems likely that antibody might be demonstrable years after recovery as in certain other diseases We have made observations on sera from a number of persons who had suffered from smallpox 1–8 years previously, most of them during the 1946 outbreak on Merseyside In these sera complement fixing antibody was no longer detectable and the titre of antihæmagglutinins was low, but all the sera showed a high level of neutralising antibody It is apparent therefore that while the two in vitro tests reveal the early antibody response during the clinical illness in persons not recently vaccinated, the antibody demonstrated is not that which is most likely to be associated with specific resistance to infection The power of a serum to prevent infection of susceptible tissue by variola virus is probably a more useful indication of an individual's resistance to the disease

Using the same techniques we have examined the sera from persons at different periods after vaccination or revaccination Antibody was not found before the 10th day after primary vaccination, but by the 13th day it was demonstrable by all three methods In smallpox, antibodies are not usually detectable before the 3rd day of illness—i e, about 15 days from the time of infection It has always been believed that the immunity response following vaccination was more rapid than that following infection in smallpox patients, and that the protection, usually though not invariably, afforded by vaccination at the time of contact could thus be explained The results of serological tests are in keeping with this belief The maximum titre was reached 3–4 weeks after primary vaccination but did not usually attain the levels reached by the smallpox convalescent sera A year after vaccination complement fixing antibody and antihæmagglutinin were not usually to be found, but in some subjects, vaccinated many years before, neutralising antibody to variola virus was still present As might be expected, the amount and persistence of antibody varied in different individuals It is well known that smallpox often attacks persons who have been successfully vaccinated years before, although the disease is frequently mild In such persons antibody may be absent from the blood or present only in low concentration, but we had details supplied by Dr W H Bradley of a nurse vaccinated 2 years before who suffered from a very mild attack of smallpox and in whose serum, taken immediately before she was infected, we found a considerable titre of neutralising antibody for variola virus It is possible that antibody in the blood deteriorates in quality as well as in quantity with the passage of time

As variola virus may be exposed to the action of antibody for only short periods between release from one cell and entry into another, it may be that only antibody of high avidity can effectively protect a person from infection of a degree that would become clinically apparent We have recently tried modifications of our technique in an attempt to measure avidity of sera—i e, speed of combination with virus So far our results have not been very conclusive

SUMMARY

It is still not possible to give a factual account of the course of events which follows human infection with the virus of smallpox Nevertheless the outline of the story seems fairly clear, and, if much detail has to be filled in by speculation, this is inevitable in our present state of knowledge As I see it, the following summary seems reasonable, although in parts it lacks supporting evidence

The site of entry of the virus to the tissues is in the upper respiratory tract At most only a minimal or closed lesion occurs in the mucous membrane and the virus quickly passes to lymphatic glands and by blood stream to internal organs Progressive infection of cells in these organs, with increase in virus, takes place during the incubation period Towards the end of this period, or at the onset of illness, there is an overflow of virus into the blood stream, and liberation of the products of cell breakdown The skin and other tissues are infected with virus at this time, and in most cases the immune response with the formation of antibody follows a few days later The speed and extent of the antibody formation determines the extent of the rash and the severity of the disease The maturation of the eruption proceeds after the antibody has appeared and is secondary to the destruction of cells infected in the first few days of illness Patients who die in the later pustular stage of the eruption may have a high titre of antibody in their sera, in such patients death is due to the late effects of earlier virus activity or to some complicating disability or infection Antibody persists at a high level for some years after smallpox After vaccination neutralising antibody may be detectable for many years, but is not usually present in as high a concentration as after smallpox and it varies considerably in different individuals The quality as well as the quantity of antibody in the blood may be of importance in determining relative immunity to smallpox infection

THE level of prothrombin in the blood of healthy nfants is low from about twelve hours after birth to he end of the fifth day of life, and the blood coagulation ime is relatively prolonged during this period (Waddell nd Guerry 1939, Dam et al 1939, Nygaard 1939, Quick and Grossman 1940) Unusually low prothrombin evels are often, but not invariably found in infants with æmorrhagic disease of the newborn Equally low levels owever, may occur without any bleeding

The discovery by Dam (1934) of vitamin K in alfalfa nd certain liver fats and his demonstration that it is ssential to the formation of plasma prothrombin (Dam 1934, Dam et al 1936), were followed in 1939 by Waddell nd Guerry's work which suggested that the administration of vitamin K to the newborn infant immediately after birth prevents the development of the usual hypoprothrombinæmia and prolongation of clotting time, or, if given later, when these changes have already taken place, ensures a rapid return to normal

Vitamin K has therefore been widely used during the past ten years in the treatment of neonatal bleeding but the results obtained to date suggest that its value in controlling bleeding is limited, and that blood transfusion is still essential in severe cases The efficiency of the vitamin in preventing hæmorrhagic disease when it is given to the infant immediately after birth is also doubtful Lehmann (1944) reported on 13 250 babies to whom vitamin K had been given within an hour of birth, and compared the incidence of hæmorrhage in them and in 17,740 babies who had not received vitamin K His results, in the opinion of THE LANCET (1944), did "not show conclusive evidence of the prophylactic value of vitamin K"

Several workers have given vitamin K to pregnant mothers shortly before delivery, and have observed the effect on the prothrombin level and blood coagulation-time of the infants during the first week of life Some also noted the incidence of bleeding in these infants

MacPherson et al (1940) gave vitamin K by mouth to 31 mothers before delivery, and reported an effect on the infants' prothrombin level similar to that obtained by giving vitamin K to the infant after birth.

Bohlender et al (1941) obtained the same result in the infants of 50 mothers to whom they gave intravenous vitamin K before delivery

Beck et al (1941) found that the administration of vitamin K to 1022 mothers in labour eliminated the neonatal fall in prothrombin level in their infants they also noted that the blood clotting time approached that of normal adults In addition they remarked that only 5 out of the 1022 infants of mothers who had received vitamin K ante partum showed hæmorrhage,' whereas in 21 of 1037 controls hæmorrhage of some sort took place

A series of 1693 infants of mothers to whom vitamin K had been given before delivery was reported by Sanford et al (1942) They too observed the raised prothrombin levels in the infants but concluded that the frequency of hæmorrhagic manifestations in their series was unaffected by vitamin K Since the incidence of hæmorrhagic disease of the newborn probably varies from 1 in 200 to 1 in 1000 infants, such a conclusion from only 1693 cases was probably unjustified

The dose of vitamin K differed in each of these series MacPherson et al (1940) concluding that 50 mg was the best dose by mouth, and Bohlender et al (1941) injecting 1 mg intravenously The time of administration before delivery also varied, MacPherson et al (1940) considering 4–12 hours to be the best time, Bohlender et al (1941) finding that all their injections from 5 minutes to 23 hours 15 minutes before delivery were successful in raising the infants' blood-prothrombin level

Poncher, in 1942, expressed his views as follows

> "So far as the effect on the prothrombin time is concerned, it can be definitely stated that if oral preparations are given to a normal pregnant woman twenty four to twelve hours before she goes into labor, or if vitamin K is administered daily before delivery, the prothrombin time of the infant will be normal and there will be no untoward effect on the mother Water soluble preparations given parenterally will be effective in prophylaxis when given as late as one hour before delivery although it is desirable to have a longer interval to obtain the maximum effect The dosage recommended is 2 mg daily of the oral preparations and a single dose of 2 mg of the water soluble parenteral preparations at least from six to four hours before delivery There would seem to be little advantage in giving oral prophylactic therapy more than a week before labor as there is no evidence for a cumulative effect In fact, a single oral dose of 5 mg at the start of the first labor pain may be practical in most cases If a woman goes into labor without adequate prophylaxis a single dose of a parenteral preparation can usually be given in a sufficient time to be effective before she delivers"

In 1944, THE LANCET published a leading article reviewing the information available at that time which summed up by saying It is probably advisable to give menaphthone either to every mother at or just before the beginning of labour or to every newborn child as a prophylactic against hæmorrhagic disease"

INVESTIGATION

The clinical experiment reported here was planned to assess the practicability of giving vitamin K to mothers in large busy maternity units and its efficacy in preventing hæmorrhagic disease of the newborn The units participating were the five largest maternity units in Liverpool the Liverpool Maternity Hospital the Mill Road Maternity Unit and the maternity units of the Broadgreen, Sefton General, and Walton Hospitals comprising 544 maternity beds and about 12,550 deliveries a year

Our intention was to administer a vitamin K analogue during labour to some 10,000 mothers and to set aside 10,000 controls during this period to whom no vitamin was given the general care and treatment of the two groups being otherwise identical The dose decided on was 50 mg given by intramuscular injection We aimed at giving vitamin K between four and twelve hours before delivery The mothers were placed in the experimental or control series by the simplest practical method of allocating the deliveries in alternate weeks to the experimental series The numbers involved and the limited laboratory facilities available precluded the estimation of blood prothrombin levels or coagulation time

As the experiment proceeded, it became clear that many mothers in the ' experimental" weeks were not receiving vitamin K before delivery, such causes as precipitate labour before or soon after admission being mainly responsible In addition many mothers' labours were shorter or longer than had been anticipated, with the result that vitamin K was administered less than four or more than twelve hours before delivery The findings at the end of two years' experiment have therefore been reviewed, and our report concerns 4602 mothers who received vitamin K under the conditions specified, and 12,136 "controls" to whom no vitamin K was administered

RESULTS

Hæmatemesis and/or melæna occurred in 34 infants Of these, 11 were born to mothers who had received vitamin K before delivery The clinical details of the 34 cases are summarised in tables I and II The difficulty of confirming the diagnosis of hæmorrhagic disease is well known Infants not infrequently vomit blood which has been swallowed at birth, and this is especially likely to happen when the mother has had an antepartum hæmorrhage In all our cases the pædiatrician seeing the case at the time bleeding occurred formed the opinion that hæmorrhagic disease was the most likely diagnosis The occurrence of bleeding other than from the stomach or the bowel has not been recorded in this analysis, owing to the difficulty of excluding other causes of such hæmorrhages, nor has intracranial hæmorrhage been considered, for the experimental and control series are not strictly comparable

Hæmorrhagic disease of the newborn occurred therefore in 11 out of 4602 infants whose mothers had received vitamin K before delivery—i e, in 1 in every 418 cases—and in 23 of 12,136 infants whose mothers had not been given vitamin K—i e, in 1 in every 527 cases

TABLE I—HÆMORRHAGIC DISEASE IN INFANTS WHOSE MOTHERS HAD NOT RECEIVED VITAMIN K

Case no	Month and year of birth	Birth weight		Delivery	Clinical details
		lb	oz		
1	10/49	6	12	Vertex	Bright red blood in stool on 3rd day
2	3/49	8	0	Vertex	Severe melæna 53 hr after birth
3	5/49	6	8	Concealed A P H, vertex forceps	Melæna on 1st and 2nd days
4	2/50	7	4	Vertex	Small hæmatemesis on 3rd day
5	9/48	5	14	Cæsarean section for eclampsia	Recurrent severe hæmatemesis starting 53 hr after birth
6	11/48	6	13	Vertex	Hæmatemesis on 2nd day
7	4/49	7	0	Vertex	Melæna on 3rd and 4th days
8	12/48	5	9	Vertex	Fairly severe melæna on 1st 2nd 3rd and 4th days
9	9/48	7	7	Vertex and forceps	Melæna and hæmatemesis on 7th day
10	2/49	8	11	Vertex	Melæna on 2nd and 3rd days
11	10/48	6	12	Vertex retroplacental clot	Hæmatemesis and melæna on 4th day
12	6/48	7	2	Cæsarean section	Melæna on 5th and 6th days
13	12/48	7	9	Cæsarean section	Melæna on 1st 2nd and 3rd days and hæmatemesis on 2nd day

DISCUSSION

In view of the great variability of the incidence of hæmorrhagic disease in previous reports this difference is not considered to be significant, but it is quite clear that in this series the administration of vitamin K to mothers in labour did not prevent hæmorrhagic disease

Poncher (1942) wrote "Vitamin K and its analogues are effective in prevention and treatment of all hypoprothrombinemic states encountered in the newborn period which are not due to extensive liver damage restoration of prothrombin levels to normal invariably follows administration of adequate doses of vitamin K (if it is given by routes which will facilitate absorption), and cessation of bleeding follows if deficiency of prothrombin is the causative factor in the hæmorrhage' If his opinion is accepted, it seems either that the administration of vitamin K did not prevent the fall of blood prothrombin level in the infants in this series, or that the bleeding was due to some cause other than prothrombin deficiency

CONCLUSIONS

Vitamin K given to pregnant women before deliver does not always prevent hæmorrhagic disease of the newborn Its administration involves additional expense and increases the demands on the already over taxed nurses of maternity units It should therefore not become part of routine treatment during labour in these units Opinions will vary about the advisability of its administration to mothers in labour, or to their infants soon afte birth, when there is an increased risk of neonatal bleedin —i e, in maternal toxæmia, premature labour, difficu or instrumental delivery, injury, asphyxia, and rhes incompatibility

SUMMARY

Vitamin K was administered to 4602 pregnant wom before delivery There were 12,131 controls Hæm rhagic disease was observed in 11 of the newborn infa of the vitamin K group (1 in 418) and in 23 of t controls (1 in 527)

It is concluded that vitamin K had no effect on t incidence of hæmorrhagic disease in this series

We wish to thank Prof N B Capon for his guidance planning this investigation, the obstetricians for th coöperation in allowing us to treat their patients, pædiatric registrars for the detailed supervision and record of the experiment and the nurses for cheerfully undertak

e additional duties involved. Messrs. Roche Products Ltd ecially prepared the 50 mg ampoules of 'Synkavit' and pplied them at reduced cost

INFECTIOUS DISEASES UNIT ROYAL FREE HOSPITAL, LONDON

EXPERIENCE in a puerperal sepsis unit has shown that while hæmolytic streptococcal infections have become mild and yield readily to penicillin therapy, generalised staphylococcal infections still present many of the same problems as in the pre-penicillin period We review here our experience of these infections in three periods—(1) pre-penicillin, (2) early penicillin, and (3) late penicillin—in the hope of throwing light on the value of penicillin therapy, the best conditions for its use, and the limitations which may necessitate the trial of other antibiotics

PRE-PENICILLIN PERIOD

Between January, 1937, and December, 1943, 23 patients with generalised infection due to *Staphylococcus pyogenes* were treated in the unit Of these, 18 followed abortion and 5 full-term delivery The 18 cases in the post abortum group constituted 36 8% of all cases in that group in which *Staph pyogenes* was isolated on cervical culture Thus the organism exhibits an invasive power far exceeding that of any other organism in puerperal infection, the corresponding figure for the hæmolytic streptococcus over the same period was 11% Of the 23 cases 10 proved fatal, a rate of 43 4%, which is lower than that of blood-stream infections due to the hæmolytic or anaerobic streptococcus in that period Chronic invalidity associated with infective foci on heart valves, in lung, and in joints was common Treatment with sulphonamides and staphylococcal antitoxin seemed to have little effect on the course of the disease

Clinically, although all cases gave repeatedly positive blood-cultures, the type of infection varied from the acutely fulminant to the subacute or chronic form which often subsided after the formation and evacuation of a single abscess Intermediate between these two extremes were the patients with widespread lesions, some of whom died after thirty to seventy days, while others recovered after a protracted course, often with residual lesions such as damaged heart valves healed lung abscesses, and chronic arthritic changes

EARLY PENICILLIN PERIOD

Between December, 1943, and April, 1946 8 cases were treated with small dosage of penicillin (i.e., about 15 000 units three hourly or four hourly), 2 were fulminant and proved fatal Of the 6 patients who recovered, only 2 showed good response to this dosage of penicillin Our early experience of penicillin in these generalised staphylococcal infections showed that (1) small dosage of penicillin, though sufficient to sterilise the blood stream even in the heaviest infections did not necessarily arrest the disease and (2) early cessation of penicillin therapy favoured relapse

The first point is illustrated by the following case

Case 23 (see table II and fig 1) was admitted on the twelfth day of disease and had bacterial counts of 3600 and 4820 organisms per ml. in the cultures made from blood taken on the first two days in hospital A course of penicillin 705,000 units in twelve days was followed by sterile cultures on the

who received vitamin K under the conditions specified, and 12,136 "controls" to whom no vitamin K was administered

RESULTS

Hæmatemesis and/or melæna occurred in 34 infants Of these, 11 were born to mothers who had received vitamin K before delivery The clinical details of the 34 cases are summarised in tables I and II The difficulty of confirming the diagnosis of hæmorrhagic disease is well known Infants not infrequently vomit blood which has been swallowed at birth, and this is especially likely to happen when the mother has had an antepartum hæmorrhage In all our cases the pædiatrician seeing the case at the time bleeding occurred formed the opinion that hæmorrhagic disease was the most likely diagnosis The occurrence of bleeding other than from the stomach or the bowel has not been recorded in this analysis, owing to the difficulty of excluding other causes of such hæmorrhages, nor has intracranial hæmorrhage been considered, for the experimental and control series are not strictly comparable

Hæmorrhagic disease of the newborn occurred therefore in 11 out of 4602 infants whose mothers had received vitamin K before delivery—i e , in 1 in every 418 cases—and in 23 of 12,136 infants whose mothers had not been given vitamin K—i e , in 1 in every 527 cases

first, second, fourth, and eighth days of its administration, but the patient died after fourteen days, and necropsy showed vegetations on the heart valves, and cerebral hæmorrhages from embolic lesions in the pons and medulla

The second point is illustrated by cases 21 and 28

Case 21 (see table II and fig 2), aged 20, was admitted two days after a three month abortion, having been pyrexial for twenty four hours The day after admission the uterus was evacuated because of hæmorrhage Ten days later the patient developed staphylococcal septicæmia The blood culture was positive on six occasions, and, despite treatment with 100 g of sulphapyridine and sulphathiazole, the bacterial count rose from 75 to 703 organisms per ml By this time a systolic bruit had developed in the pulmonary area The patient was next given a course of 790,000 units of penicillin in seven days, pyrexia subsided and two consecutive blood cultures were sterile Three days after penicillin had been stopped the pyrexia recurred and blood culture produced *Staph aureus* 167 organisms per ml After a course of 870,000 units of penicillin pyrexia again subsided and three consecutive blood cultures proved sterile After two weeks a second relapse occurred with two positive blood cultures and a count of 187 organisms per ml A third course of 375,000 units of penicillin was given and this finally controlled the septicæmia, seven consecutive sterile blood cultures being obtained Owing to the development of endocarditis convalescence was protracted and the patient was finally discharged from hospital after a stay of one hundred and ninety one days

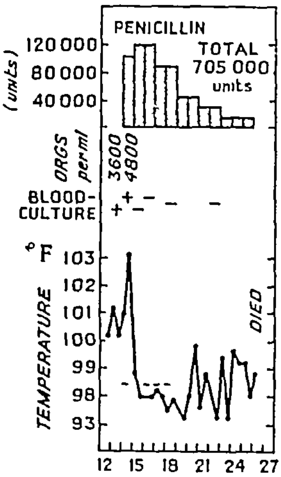

Fig 1—*Staph aureus* septicæmia with mitral stenosis with recent vegetations subdural hæmorrhage septic splenic infarcts and chronic nephritis (case 23, table II)

Case 28 (see table II), aged 23, became pyrexial eight days after an abortion and was admitted to a general hospital *Staph aureus* was grown both from the vaginal swab and on blood culture Arthritis of the right wrist and knee developed, and radiography of the chest showed patchy consolidation of the right middle and lower zones The patient was treated with penicillin 700,000 units and sulphathiazole 28 g in five days and transferred to the unit twelve days after the commencement of her illness As in the previous case, a succession of small courses of penicillin did not arrest the disease, and successive blood cultures gave bacterial counts of 580, 1200, and 2800 organisms per ml Improvement finally took place after a course of penicillin 1,875,000 units in fourteen days This was maintained for two weeks, when a further relapse necessitated a course of penicillin 1,540,000 units in seventeen days *Staph aureus* was isolated from the sputum on 47 occasions in sixty nine days and was penicillin sensitive throughout Septicæmia in this case resulted from the constant reinfection of the blood from multiple lung foci The patient was finally discharged from hospital after a stay of one hundred and ninety-eight days

As a result of these and similar cases in this period it was felt that more intensive and prolonged dosage of penicillin was required from the outset in this type of case

LATE PENICILLIN PERIOD

At the beginning of this period 5 cases were treated with penicillin 500,000 units three hourly from the time the diagnosis was made This had the effect of immediately arresting embolic spread and shortened considerably the stay in hospital Cases 34 and 36 had penicillin resistant strains of organism

Case 34 (table III), aged 35, was admitted on the thirty-fifth day of illness with low grade septicæmia and much enlarged liver and spleen A highly resistant strain of *Staph aureus* sensitive to 6 25 units of penicillin per ml was isolated from the blood on seven consecutive days, the highest bacterial count was 10 organisms per ml Clinical improvement did not take place until the dose of penicillin was raised to 500 000 units three hourly

Case 36 (table III), aged 18, became infected after cæsarean section performed at the twenty eighth week of pregnancy because of toxæmia The patient became pyrexial from the day of operation She was given a course of penicillin in gradually increasing doses over eleven days Within twenty four hours of the end of the course an embolic mid tarsal arthritis developed The patient was next transferred to the unit, and penicillin therapy was started again in doses of 500,000 units three hourly for four days and thereafter in reduced dosage for nine days A total of 29 mega units was given Pyrexia subsided within twenty four hours of the commencement of treatment, and the affected joint did not suppurate

Case 32 (table III), aged 33, comparable to case 28 above had bilateral purulent pleural effusions, and 35 colonies of penicillin sensitive *Staph aureus* per ml were found in the blood There were multiple skin emboli and red cells in the urine The patient was given 4 mega units of penicillin daily for eleven days and thereafter 2 mega units daily for fourteen days She was discharged after sixty one days in hospital

Case 33 (table III and fig 3), aged 30, with peritonitis and pulmonary abscesses, responded satisfactorily to penicillin 500,000 units three hourly for nine days The dose was then reduced too rapidly, and the patient developed an infection in the right sternoclavicular joint Penicillin 500,000 units six hourly was given for nineteen days before activity in

TABLE II—EARLY PENICILLIN PERIOD

37	P.A	F	8	+	5	21	Sensitive to 0 6 units/ml on admission 3 days later sensitive to 20 units/ml.	14 000 000	Died	*P M* pulmonary, renal and cerebral abscesses
38	P A.	P	27	+	2		Sensitive	25,250 000	Died	*P M* endocarditis, cerebra abscesses renal necrosis

the joint completely subsided. The organism was penicillin sensitive

It was felt that massive dosage of penicillin from the earliest possible moment, and avoidance of the temptation to withhold penicillin merely because pyrexia had subsided, might provide the key to treatment of both the resistant strain of organism and the latent and inaccessible focus of infection Recent experience, however, suggests that penicillin may not be the final answer to the problem of generalised staphylococcal infection Two cases illustrate well the difficulties still encountered.

Case 37 (table III) aged 28, was admitted eleven days after an abortion A year previously the patient had had a nephrectomy for hydronephrosis, this was complicated by empyema, for which penicillin was administered before the empyema was drained There had been intermittent discharge from the nephrectomy wound since the operation

On admission the patient was shocked and pale The hæmoglobin was 30% Two pints of blood was given, and under general anæsthesia a large mass of putrefying placenta was removed

Progress—Next day the patient was still pyrexial the hæmoglobin had risen to 42% the venous pressure was raised and the liver was palpable 3 in below the costal margin The blood pressure was 95/40 Next day a systolic murmur was heard at the pulmonary base The patient had neck rigidity and a positive Kernig sign The cerebrospinal fluid (C.S.F.) contained 1660 cells per c.mm (polymorphs 98%) and total protein 60 mg per 100 ml The nephrectomy sinus was discharging

Treatment was begun with penicillin 500 000 units three hourly After a loading dose of 4 g, Sulphatriad was given in doses of 1 g three hourly The treatment was continued until death but did not sterilise the blood stream A further transfusion was given Next day the patient became comatose and died in six hours

Blood-cultures were positive on five occasions in five days, and the bacterial count did not exceed 21 organisms per ml The organism obtained from the blood and the nephrectomy wound were of the same phage type When first obtained from the blood the organism was sensitive to penicillin 0 6 unit per ml The organism obtained from the blood the day before the patient died was sensitive to penicillin 20 units per ml

Necropsy showed purulent fluid in the lateral ventricles and an area of softening in the pons The left lung was adherent to the chest wall, there were two septic infarcts one in the upper and the other in the lower lobe of the left lung The heart valves were healthy but the muscle showed toxic changes There was a small amount of renal tissue left associated with chronic inflammation A sinus extended

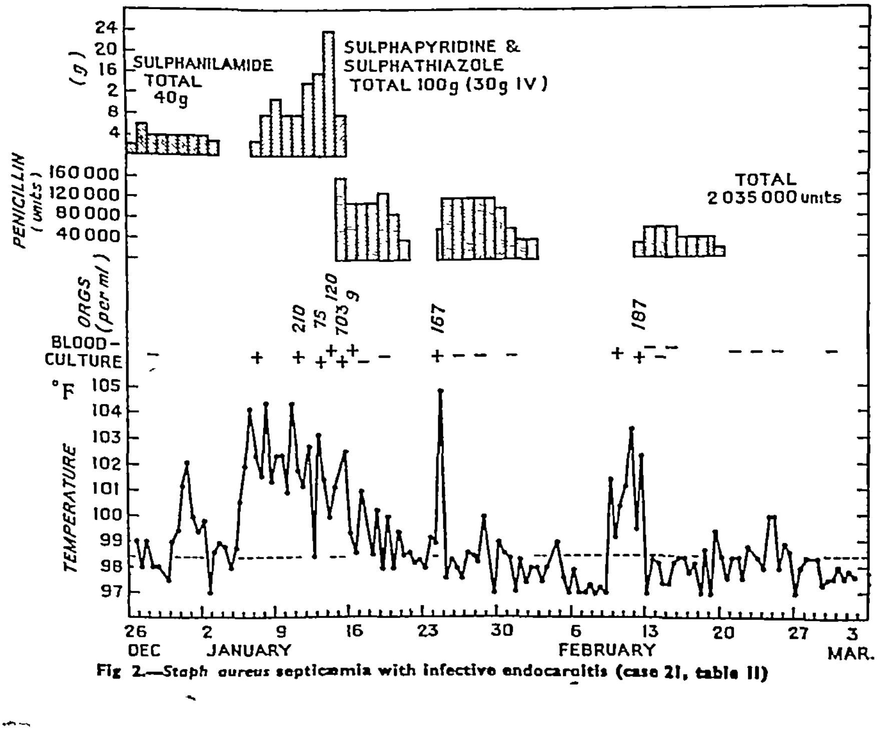

Fig 2.—*Staph aureus* septicæmia with infective endocarditis (case 21, table II)

TABLE I—RESULTS OF TREATMENT AND TOXIC EFFECTS WITH LYSIVANE

Toxic Symptoms

Drowsiness	7	Pressure on head or head ache	4
Ataxia	7	Flushing of face	3
Muzziness or confusion	6	Slurred speech	3
Blurred vision	6	Nausea and vomiting	2
Lightheadedness or giddiness	6	Dryness of mouth	2
Derealisation or depersonalisation	4	Stiffness worse	2
" Funny feelings "	4	Tremor worse	1
		Oculogyric crises worse	2

When examined on Dec 9, 1948, his face was immobile and there was a moderate increase of tone in the right arm and leg, but there was no tremor He held his right hand flexed and did not swing it when walking His gait was shuffling, and he dragged the right leg

Treatment —Initially he was given 'Rabellon' tab 1 t d s without any improvement He began taking parpanit on Jan 20, 1949, and when he was taking 75 mg six times a day there was considerable improvement but he complained of nausea and occasional vomiting He remained free from toxic symptoms on 50 mg six times a day On Sept 29, lysivane was gradually substituted for the parpanit, the initial dosage of 50 mg t d s being increased later to 50 mg ten times a day This dose caused some retching and was therefore reduced to 50 mg eight times a day

Progress —The patient noted much more improvement than with parpanit He said he could pick coins out of his pocket with his right hand much more easily and could sit down and rise to his feet more quickly, his writing improved, and the dragging of his right leg disappeared On later visits he said " There is no further improvement because there is nothing to improve on " The immobility of his facies was still obvious though improved, and tone in the right arm and leg was now normal In March, and again in April, 1950, he was given artane in addition to the lysivane, but on each occasion it was discontinued because of nausea and vomiting No added effect was noticed Artane was not tried alone

This was a mild case which improved considerably on lysivane

Case 2 —*Severe postencephalitic* A man, aged 37, had had encephalitis lethargica in 1925 Rigidity and tremor began in the left arm in 1930 and slowly progressed to involve the left leg He developed a festinant gait with dragging of the left foot and a mask like facies and was having oculogyric crises about once a week, each lasting up to three hours

Treatment —He had been taking tincture of hyoscyamus min. 70 t d s this was stopped, and lysivane 50 mg t d s was started on Jan 25, 1950 and increased by 50 mg daily At first the dosage was halted at 600 mg daily, by which time the duration of the oculogyric crises had been reduced to 20 minutes and there was slightly less rigidity Next the dosage was increased by daily increments of 50 mg to 750 mg daily, with marked subjective improvement, his posture noticeably improved, and he was free from oculogyric crises for seven days Then the dosage was slowly increased in the next three weeks to 1500 mg daily His gait improved, the oculogyric crises were still infrequent, he was cheerful, and for the first time for years he became useful in the ward He still receives 1500 mg of lysivane daily and has not had any unpleasant side effects

This case was assessed as moderately improved

Case 3 —*Severe postencephalitic* A man, aged 39 It was not possible to obtain any accurate history of the onset of his condition, he had a mask like facies and was having three or four oculogyric crises every week, each lasting up to nine hours Well marked tremor was present in the tongue, jaw, and right arm and leg, with typical cog wheel rigidity, a flexed posture, and a tendency to propulsion and retropulsion He could not dress, do his hair, or feed himself Dysarthria was severe, and he had frequent severe attacks of hyperkinesia accompanied by behaviour disorders.

Treatment —He had been receiving tinct hyoscyami min. 75 daily He was now given lysivane 50 mg t d.s. and the hyoscyamus was gradually withdrawn in the next seven days, while the lysivane was increased by 50 mg daily to 300 mg a day In a fortnight he could feed himself for the first time in years The dose was gradually increased to 500 mg daily He began to feel and look better, his face became more animated, his speech was slightly easier to understand, his behaviour disorders were less frequent, the duration of his oculogyric crises was reduced to 20 minutes, and he could dress himself Little further improvement occurred over the next four weeks, though the dosage was raised to 1500 mg daily for three weeks He then complained that the tablets made him dopey and confused With difficulty he was persuaded to persevere with them, and he was also given 10 mg of amphetamine sulphate daily, with no improvement. He still complained of feeling queer on the tablets and refused to take any more A change was made to artane starting with 5 mg t d s and increasing to 30 mg daily with no ill effects The greatest improvement that had been reached with lysivane was maintained by artane in this dose Oculogyric crises became rare and less severe For the first time in many years the patient was fit to be entrusted with ward work

This case was assessed as moderately improved with lysivane, though the patient could not tolerate a long course of this drug His improvement was then maintained with artane

TOXIC EFFECTS OF LYSIVANE

Of the 43 patients who received lysivane, 24 complained of unpleasant side effects, and in 9 cases these were sufficiently troublesome to necessitate discontinuing the drug The symptoms were never alarming and always subsided rapidly on the withdrawal of lysivane In only one case was there any untoward result a patient with idiopathic parkinsonism became ataxic, fell, and sustained a crush fracture of D12 and L1 vertebræ Most of the patients who experienced side effects complained of several symptoms The details are given in table II

Four patients developed mild depersonalisation, and 4 others complained of " funny feelings " which seemed to be in the same category Only one had to stop the treatment, in the others the sensation was transient, mild, and either subsided spontaneously or as a result of reduction in the dosage of lysivane

Accentuation of symptoms was observed in 5 patients —rigidity in 2, oculogyric crises in 2, tremor in 1—and in 3 cases this necessitated the discontinuance of lysivane, it proved transient in the other 2 (1 with increased rigidity and 1 with increased tremor)

As a result of a warning from the manufacturers of lysivane about the possibility of agranulocytosis, frequent white cell counts were made in all the cases No leucopenia was observed

RESULTS WITH ARTANE

Artane was given to 51 patients with results which are summarised in table II Of the 31 postencephalitics, 24 were improved, 5 unaffected, and 2 became worse, of the 16 idiopathic cases, 11 were improved and 5 unchanged, one arteriosclerotic was greatly improved whereas the other was unaltered, and 2 patients with extrapyramidal disorders of obscure ætiology were symptomatically improved Altogether, 38 of the 51 cases derived some benefit, 11 were unchanged, and 2 became worse

Illustrative Cases

Case 4 —*Moderate idiopathic* A man, aged 57 When examined on Jan. 25, 1950, he had a mask like facies and tremor with moderate rigidity of both arms His gait was little affected but he did not swing his arms

Treatment and Progress —Artane was started with 2 mg t d.s and increased to 5 mg t d s At first there was little improvement except that the face was more animated, but in the fourth week his tremor ceased, and at the end of a month his rigidity had also improved Some side-effects were now noted, particularly transient diplopia on upward deviation of the eyes Troublesome flushing and sweating also occurred after taking the tablets and, on the chance that these symptoms might be due to liberation of histamine, he was given phenergan 25 mg at night, with considerable benefit

This case is assessed as moderately improved

Case 5 —*Moderate postencephalitic* A man, aged 47, had noted increasing weakness and tremor of his right arm since 1944 A year after the onset the right leg became similarly affected His only previous treatment had been physiotherapy and benadryl When he was examined on Jan 25 1950, his facial expression seemed normal but tremor and cog wheel rigidity of moderate severity were present in the right arm and leg He did not swing either arm on walking, and his gait was slow

Treatment and Progress —He was started on artane 2 mg t.d.s which was rapidly increased to 5 mg t d s Within seven days he felt much more alert but there was little alteration in his physical signs, and the dose was therefore increased to 17 5 mg daily

Here the patient thought his condition was vastly improved, but the improvement was assessed as only moderate

Case 6 —*Severe postencephalitic* A woman, aged 34, an example of the completely helpless cases Her history is unknown She had a mask like facies, was having oculogyric crises lasting three hours two or three times a week, there was intense cog wheel rigidity of all her limbs, and severe contractures had formed in all her major joints, so she was incapable of attending to her bodily needs

Treatment had been with tincture of stramonium in high dosage Artane 2 mg t d.s was started on Jan. 9 1950 and a slight reduction in rigidity soon became apparent Amphetamine sulphate 10 mg daily was then given in addition. In the next fortnight she improved further and for the first time for many years she printed her name Artane and amphetamine sulphate were gradually increased until Feb 27 she was receiving 35 mg of artane daily in seven doses and one morning dose of 20 mg of amphetamine sulphate Movement was now possible at most joints to an extent limited by the contractures Oculogyric crises now occurred once or twice a week and usually lasted only one or two hours Improvement continued In March she could adjust her hair slide and soon afterwards she wrote her first letter for many years Artane has been slowly increased to 80 mg daily in six divided doses, and amphetamine sulphate to 25 mg b d

The parkinsonism in this case has been materially improved, but contractures prevent the patient taking full advantage of the reduction in rigidity, and she remains almost completely helpless She was assessed as slightly improved

TOXIC EFFECTS OF ARTANE COMPARISON WITH LYSIVANE

Though 19 patients complained of side effects (table II), in only 3 was it necessary to discontinue treatment Up to now, changes in the blood picture have not been noted in any of the patients

The difference in the toxic effects of lysivane and artane is not fully brought out in the tables On the whole the symptoms produced by artane were trivial and certainly less severe than those seen with lysivane The difference is seen best in the numbers of cases where the drugs had to be discontinued—with lysivane 9 patients out of 43, and with artane only 3 out of 51 It should be noted too that patients who developed multiple side effects on one drug were likely to develop similar symptoms on the other, and such patients often developed toxic symptoms with the other drugs used in the treatment of parkinsonism, particularly parpanit and diparcol Rapid withdrawal of either artane or lysivane seemed to be quite safe In 4 cases in which the parkinsonian symptoms had improved, a change to dummy tablets caused a dramatic return of their former severity, but in no case could any symptoms be ascribed to the actual withdrawal.

DISCUSSION

In lysivane and artane we have two potent substances for the relief of some of the symptoms and signs of parkinsonism There seems to be no sure method of forecasting whether a particular case will respond satisfactorily to either compound, except that cases which have not responded to other substances in adequate doses seem likely to resist the beneficial effects of artane or lysivane, whereas if there has been some response to other remedies better results are likely to follow a change to one of these two substances

The few published reports of cases treated with artane agree to a remarkable extent in the percentage of cases responding favourably Thus Doshay and Constable (1949), report 117 cases, with 76 1% improved , Corbin (1949) 80 cases with 76 9% improved , Ellenbogen (1950) 12 cases with 66% improved , and Phillips et al (1950) 35 cases with 80% improved In the present series the improvement rate was similar—74 5% improved out of the 51 cases treated with artane Like most of the other observers cited, we found that postencephalitic cases required, and tolerated, higher doses than the other varieties. We have given our patients much larger doses than those reported by other workers A few of our cases are now receiving 60–100 mg of artane daily with a striking absence of side effects, though the average is about 50 mg daily Artane often gives patients a feeling of well being over and above that which might reasonably be expected to follow the relief of symptoms

Ellenbogen (1950) and Phillips et al (1950) state that doses higher than 35–45 mg daily cause no additional improvement in the postencephalitic In the present series, on the contrary, it was found necessary in most cases to exceed 50 mg before the full benefit was obtained In many postencephalitic cases amphetamine has a potentiating effect on artane, this is a firm clinical impression though difficult to assess quantitatively

Hitherto no series of cases treated with lysivane has been published In the present series 72% of the patients who received lysivane showed some degree of improvement, compared with 74 5% with artane In general, however, the improvement obtained with artane is somewhat greater than with lysivane 8 out of 51 cases (16%) showed "great improvement" with artane, compared with only 3 out of 43 (7%) with lysivane Artane is decidedly less toxic than lysivane, and of the 9 patients who were intolerant to lysivane in the present series, all but 2 were able to take artane later, though some had slight toxic symptoms Moreover, the side effects that occurred were in general less severe with artane than with lysivane Either lysivane or artane can be rapidly withdrawn with no other ill effect than a sudden return of symptoms in their previous severity

Most of the 24 patients treated with both lysivane and artane preferred the artane This was related to its greater efficiency, its lower toxicity, and the sense of well being that artane produces Nevertheless, some patients derived equal benefit from the two drugs, and a few were decidedly better on lysivane

Most of the severe postencephalitic cases treated with artane and amphetamine sulphate were in a distressing state of almost complete immobility None were capable of ward duties Since the introduction of artane and amphetamine sulphate treatment there has been a striking change in the atmosphere of the ward Most patients can now feed themselves, and many can dress and attend to their own toilet A few can get about, though with difficulty, and some have taken on simple ward duties Apart from the benefit to the patients themselves this has considerably lightened the nurses' tasks

Both artane and lysivane seem to reduce the rigidity more than the tremor, but occasionally the tremor becomes more marked as an extreme degree of rigidity (which had previously masked it) becomes less In many instances tremor also was remarkably reduced This was particularly striking in a patient with severe tremor of the right arm following a vascular lesion (Benedikt's syndrome), in which artane 5 mg four times a day produced a dramatic improvement, which has been maintained up to date

Artane has some effect in reducing the number and duration of oculogyric crises In one woman who had previously been having an attack lasting four hours once a week, since treatment with artane, the attacks have occurred every 10–14 days and have lasted only one or two hours Lysivane seemed equally effective in this respect Thus a man who previously had two oculogyric crises lasting about three hours every week, when taking a daily dose of 1250 mg of lysivane had more than a week between attacks, and the attacks lasted only an hour Neither of these cases received any amphetamine sulphate

SUMMARY AND CONCLUSION

Artane and lysivane have been used in the treatment of 70 cases of parkinsonism 51 patients receiving artane, 43 lysivane, and 24 both drugs at different times Improvement was noted in 74 5% with artane, and in 72% with lysivane

Both artane and lysivane control the rigidity better than the tremor Both reduce the number and duration of oculogyric crises in postencephalitic parkinsonism

Higher dosage of artane than that reported by other workers has been used with good effect and minimal side effects

The action of artane is often enhanced by amphetamine sulphate in postencephalitics

Artane is less likely to produce unpleasant side-effects than lysivane, and for this reason is likely to prove the drug of choice for most cases of parkinsonism

I am indebted to Dr Macdonald Critchley, of King's College Hospital, and Dr W A Caldwell, physician superintendent, West Park Hospital, Epsom, who allowed access to their cases and encouraged this present investigation, Dr W R Thrower for his help, and Messrs May and Baker Ltd for supplies of lysivane

THE DUST CELLS IN THE LUNGS OF THE ALBINO MOUSE*

THEIR STRUCTURE, RELATIONS, AND MODE OF ACTION

Charles Clifford Macklin
M D, Ph D Toronto, F R S C
RESEARCH PROFESSOR OF HISTOLOGY, UNIVERSITY OF WESTERN ONTARIO, LONDON, CANADA

Dust cells are phagocytes which have developed in the pulmonary alveoli of man and other mammals and ingest particles of carbon and other material entering the lung with the inspired air In man the dust cells are seen under unfavourable conditions in ordinary sections, because the available lungs are often diseased, putrefied, and imperfectly fixed The lungs of the albino mouse, however, offer excellent opportunity to study the dust cells both in their normal forms and relations and under experimental conditions The results of such study may aid in the understanding of alveolar phagocytes in man

SUMMARY OF OBSERVATIONS

Dust cells are fundamentally mural phagocytes

When normal lungs of albino mice and other mammals are quickly fixed without previous collapse, the alveolar phagocytes (dust cells) are found almost exclusively attached to the alveolar walls rather than free (figs. 1 and 2) This means that under normal conditions they are sessile Counts made on thin stained sections of such material show as many as 99% or more of the dust cells morphologically affixed to the alveolar walls

Free dust cells in uncollapsed normal alveoli are few

In normal lung tissue fixed without previous collapse a few alveolar phagocytes are found free in the alveoli these are usually round or ovoid Counts show as few as 1% or less in this untethered condition, these are regarded as cells whose phagocytic potencies have been expended They have been loosened from their moorings in the alveolar walls, and would probably have found their way to the ciliary escalator of the bronchial tree

Methods of fixation without collapse

For the demonstration of dust cells in their normal habitat on the alveolar walls in the mouse, the method of immersion of the fresh flayed unopened thorax in fixing solutions such as Regaud's or Bouin's at room temperature was found satisfactory For larger animals, as well as the mouse, the method of perfusion of fixing solution through the pulmonary vasculature of the unopened thorax gave good results

Freeing of mural phagocytes by collapsing the lungs and refilling with fixative

In fresh normal mouse lungs which were collapsed and promptly filled via the trachea with fixing solution most of the alveolar phagocytes were free in the alveoli and only 5% (by actual count) remained definitely fixed in the alveolar walls This is taken to mean that the operation of collapse and refilling dislodges the alveolar phagocytes from the walls The free cells were usually irregular in outline Lungs of the dog and other mammals also showed a much larger number of free alveolar phagocytes after the collapse refill technique than after the vascular perfusion method This finding may help to explain the common view of alveolar phagocytes as free cells rather than as tethered cells

---

* Given at the International Anatomical Congress, Oxford, July 27, 1950

Freeing of mural phagocytes by collapse alone

In mouse lungs which had been collapsed, cut up, and fixed by immersion of the pieces, free dust cells were found in the alveoli which remained partially open , and in larger numbers than in the lungs fixed without previous collapse This is taken to mean that collapse alone dislodges many of the phagocytes formerly affixed in the alveolar walls In dog lungs fixed by vascular perfusion of the unopened thorax, free alveolar phagocytes were fairly abundant in local areas of partial collapse, whereas in the surrounding normally distended parts they were scarce

Free dust cells in alveolar exudate

In certain mammalian lungs fixed by vascular perfusion of the unopened thorax, some of the alveoli contained serofibrinous exudate, and in these the number of free dust cells was much greater than in the normal alveoli of the same lungs This suggests that the presence of fluid in the alveoli favours a shedding of mural phagocytes from their walls The possibility of ingress of phagocytes from other sources later on in this condition is admitted

No observed apparent entering of connective tissue by alveolar phagocytes

No unequivocal evidence was found of alveolar phagocytes apparently in the act of entering the interstitium of the lung from the alveoli, either in this series of animals or in thousands of sections of lung tissue examined during several decades If the dust cells were in the habit of making their way into the connective tissue spaces of the lung they should often be arrested en route, and would then be seen in process of leaving the alveoli and possibly the respiratory bronchioli also , but the testimony of the sections does not support this hypothesis Apparently neither the alveolar nor the bronchial walls are penetrated by the spent alveolar phagocytes The mode of insertion of the phagocytes into the alveolar walls may have erroneously led to the assumption that they were entering the connective tissue

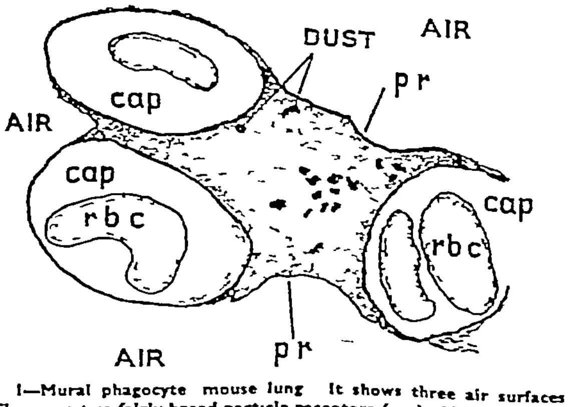

Fig 1—Mural phagocyte mouse lung It shows three air surfaces There are two fairly broad particle receptors (p.r) Note the closeness of association with the capillaries (cap) containing red cells (r.b c.) The larger black grains are dust particles some of which overlie the nucleus which is lightly outlined (Wright's stain × 4500)

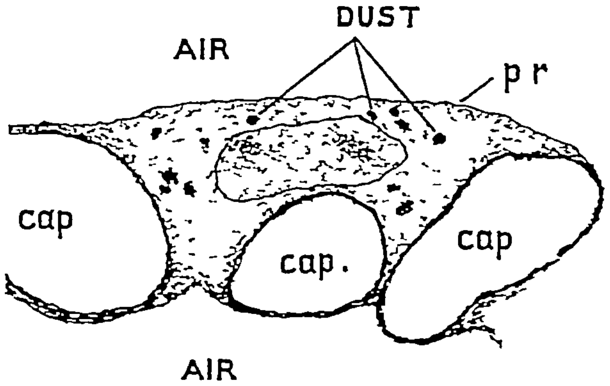

Fig 2—A mouse mural phagocyte with a broad particle receptor (p r) above and two processes directed downward separated by a capillary (Harris hæmatoxylin Fast green , × 4500)

Evacuation of spent alveolar phagocytes via the bronchial tree

In mice and all other mammals studied there is abundant evidence of dust cells in the mucous film of the bronchioli and bronchi , these are probably spent phagocytes being wafted to the region of the glottis by ciliary action They are recoverable from sputum, as Hayek (1950) and others have noted When so found they are termed " heart failure cells "—a designation of dubious value This route of elimination is regarded as the only one available for these used dust cells (Macklin 1950)

Tissue phagocytes of the lung (histocytes, histiocytes)

The dust-laden cells in the connective tissues of the lungs of man and other mammals which often appear in groups around arteries, veins, and parts of the bronchial tree, and in and around the lymphatic channels and nodes, are regarded as histocytes which have obtained their loads from stray dust particles which have eluded the alveolar phagocytic guards and have worked their way into the connective tissue Superficially these cells resemble the alveolar phagocytes in some ways, and particularly because of their content of dust particles They remain in situ for long periods and tend to gather in clumps In this view there are two kinds of dust cells (1) alveolar phagocytes of endodermal origin which take in dust particles *only from air surfaces* , and (2) histocytes of mesodermal origin, which take in dust particles *only from the connective tissue spaces* The latter type is here referred to only incidentally The view, still current, that spent alveolar dust cells are disposed of by way of the lymphatic system of the lung is regarded as unsupported by evidence Hayek has also noted these two different kinds of dust containing phagocytes in the lung

Seating of alveolar dust cells

Most alveolar wall phagocytes are in alveolar angles with processes inserted into tunnels through the alveolar walls which are encircled by capillary loops , others, resting on connective tissue, are placed in sockets, similarly environed These receptacula apparently anchor the phagocytes and provide them with means of obtaining nutriment , and their surfaces may be looked on as basement membranes, in the sense that this term is used by Ham (1950), permitting interchange of materials between the blood and the phagocyte Originally an epithelial cell, the alveolar dust cell continues to be a surface cell , but it secures itself more firmly and enlarges its area of contact with blood capillaries by sinking and branching A demonstration of the often branched nature of the mural phagocytes and their insertion into alveolar pores has been provided by fresh lungs washed with an ammoniacal silver solution and cut into sections (Macklin 1949) obtained In many postencephalitic cases amphetamine has a potentiating effect on artane, this is a firm clinical impression though difficult to assess quantitatively

Hitherto no series of cases treated with lysivane has been published In the present series 72% of the patients who received lysivane showed some degree of improvement, compared with 74 5% with artane In general, however, the improvement obtained with artane is somewhat greater than with lysivane 8 out of 51 cases (16%) showed "great improvement" with artane, compared with only 3 out of 43 (7%) with lysivane Artane is decidedly less toxic than lysivane, and of the 9 patients who were intolerant to lysivane in the present series, all but 2 were able to take artane later, though some had slight toxic symptoms Moreover, the side effects that occurred were in general less severe with artane than with lysivane Either lysivane or artane can be rapidly withdrawn with no other ill effect than a sudden return of symptoms in their previous severity

Most of the 24 patients treated with both lysivane and artane preferred the artane This was related to its greater efficiency, its lower toxicity, and the sense of well being that artane produces Nevertheless, some patients derived equal benefit from the two drugs, and a few were decidedly better on lysivane

Most of the severe postencephalitic cases treated with artane and amphetamine sulphate were in a distressing state of almost complete immobility None were capable of ward duties Since the introduction of artane and amphetamine sulphate treatment there has been a striking change in the atmosphere of the ward Most patients can now feed themselves, and many can dress and attend to their own toilet A few can get about, though with difficulty, and some have taken on simple ward duties Apart from the benefit to the patients themselves this has considerably lightened the nurses' tasks

Both artane and lysivane seem to reduce the rigidity more than the tremor, but occasionally the tremor becomes more marked as an extreme degree of rigidity (which had previously masked it) becomes less In many instances tremor also was remarkably reduced This was particularly striking in a patient with severe tremor of the right arm following a vascular lesion (Benedikt's syndrome), in which artane 5 mg four times a day produced a dramatic improvement, which has been maintained up to date

Artane has some effect in reducing the number and duration of oculogyric crises In one woman who had previously been having an attack lasting four hours once a week, since treatment with artane, the attacks have occurred every 10–14 days and have lasted only one or two hours Lysivane seemed equally effective in this respect Thus a man who previously had two oculogyric crises lasting about three hours every week, when taking a daily dose of 1250 mg of lysivane had more than a week between attacks, and the attacks lasted only an hour Neither of these cases received any amphetamine sulphate

SUMMARY AND CONCLUSION

Artane and lysivane have been used in the treatment of 70 cases of parkinsonism 51 patients receiving artane, 43 lysivane, and 24 both drugs at different times Improvement was noted in 74 5% with artane, and in 72% with lysivane

Both artane and lysivane control the rigidity better than the tremor Both reduce the number and duration of oculogyric crises in postencephalitic parkinsonism

Higher dosage of artane than that reported by other workers has been used with good effect and minimal side effects

The action of artane is often enhanced by amphetamine sulphate in postencephalitics

Artane is less likely to produce unpleasant side-effects than lysivane, and for this reason is likely to prove the drug of choice for most cases of parkinsonism

I am indebted to Dr Macdonald Critchley, of King's College Hospital, and Dr W A Caldwell, physician-superintendent, West Park Hospital, Epsom, who allowed access to their cases and encouraged this present investigation, Dr W R Thrower for his help, and Messrs May and Baker Ltd for supplies of lysivane

THE DUST CELLS IN THE LUNGS OF THE ALBINO MOUSE *

THEIR STRUCTURE, RELATIONS, AND MODE OF ACTION

CHARLES CLIFFORD MACKLIN
M D, Ph D Toronto, F R S C
RESEARCH PROFESSOR OF HISTOLOGY, UNIVERSITY OF WESTERN ONTARIO, LONDON, CANADA

DUST cells are phagocytes which have developed in the pulmonary alveoli of man and other mammals and ingest particles of carbon and other material entering the lung with the inspired air In man the dust cells are seen under unfavourable conditions in ordinary sections, because the available lungs are often diseased, putrefied, and imperfectly fixed The lungs of the albino mouse, however, offer excellent opportunity to study the dust cells both in their normal forms and relations and under experimental conditions The results of such study may aid in the understanding of alveolar phagocytes in man

SUMMARY OF OBSERVATIONS

Dust cells are fundamentally mural phagocytes

When normal lungs of albino mice and other mammals are quickly fixed without previous collapse, the alveolar phagocytes (dust cells) are found almost exclusively attached to the alveolar walls rather than free (figs. 1 and 2) This means that under normal conditions they are sessile Counts made on thin stained sections of such material show as many as 99% or more of the dust cells morphologically affixed to the alveolar walls

Free dust cells in uncollapsed normal alveoli are few

In normal lung tissue fixed without previous collapse a few alveolar phagocytes are found free in the alveoli these are usually round or ovoid Counts show as few as 1% or less in this untethered condition, these are regarded as cells whose phagocytic potencies have been expended They have been loosened from their moorings in the alveolar walls, and would probably have found their way to the ciliary escalator of the bronchial tree.

Methods of fixation without collapse

For the demonstration of dust cells in their normal habitat on the alveolar walls in the mouse, the method of immersion of the fresh flayed unopened thorax in fixing solutions such as Regaud's or Bouin's at room temperature was found satisfactory For larger animals, as well as the mouse, the method of perfusion of fixing solution through the pulmonary vasculature of the unopened thorax gave good results

Freeing of mural phagocytes by collapsing the lungs and refilling with fixative

In fresh normal mouse lungs which were collapsed and promptly filled via the trachea with fixing solution

---

* Given at the International Anatomical Congress, Oxford, July 27, 1950

umb bell shaped alveolar phagocytes

After exposure to much dust a phagocyte occupying single pore may appear with both ends swollen and the iddle constricted Such cells cannot be released from ie pore They represent a special type of pore affixation, nd are not necessarily to be considered as in act of assing from one alveolus to another

CONCLUSIONS

Alveolar dust cells under normal conditions are ttached to the alveolar walls by insertion into pores r sockets From the environing capillaries of these mplacements they derive their nutriment When spent ey become free and are disposed of via the bronchial tree

They never enter the connective tissue of the lung, d hence are never found in the lymphatic system ey are of endodermal origin and thus are epithelial type They are not to be confused with the histocytes the connective tissue of the lung, which often take dust particles which have adventitiously penetrated e alveolar walls

Alveolar dust cells are readily dislodged from the veolar walls by collapsing the lung Their vacated tes of attachment in partitional alveolar walls are iown as pores They also become free in the presence fluid in the alveoli, and gradually after experimental posure to dust such as that of carmine granules

They may have as many as four air faces or particle ceptors, and these may extend as thin flanges over ighbouring capillaries

To display them in normal relation to the alveolar all an adequate fixation technique is imperative, such prompt immersion of the fresh skinned unopened iorax in Bouin's or Regaud's fluid

I wish to thank the National Research Council of Canada r aiding this research project with a grant for technical sistance, and Mr Charles E Jarvis for his excellent work in e preparation of the material and photomicrographs

INCIDENCE OF PENICILLIN-RESISTANT AND STREPTOMYCIN-RESISTANT STAPHYLOCOCCI IN A HOSPITAL

PHYLLIS M ROUNTREE
D Sc Melb, Dip Bact

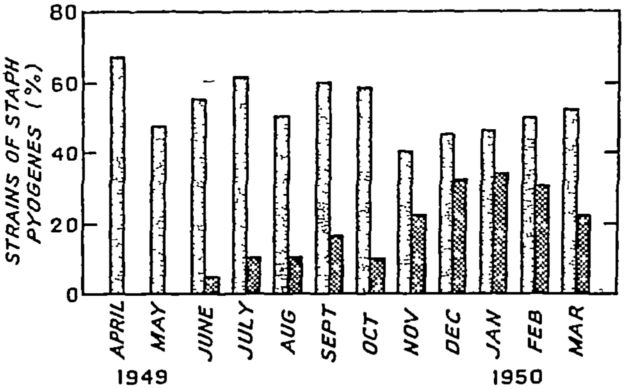
R G H BARBOUR
B Sc Agr Sydney

EDGAR F THOMSON
M.B N Z, F.R A C P

rom the Fairfax Institute of Pathology, Royal Prince Alfred Hospital, Sydney, Australia

In a previous communication (Rountree and Thomson 949) it was reported that 92 (47%) of 196 patients elded penicillin resistant strains of *Staph pyogenes*, ad 7 (3 5%) yielded streptomycin resistant strains We ive continued our examination of all strains of *Staph yogenes* isolated in this hospital, and we now record ir findings during the twelve months from the beginning April, 1949, to the end of March, 1950

In calculating the incidence of resistant strains we ave used in the present series the numbers of patients ther than the numbers of cultures examined No more ian one culture from each patient has been included nless there was a change in phage type during the atient's stay in hospital We have also distinguished between inpatients and outpatients The laboratory methods have remained the same as those previously described



Monthly incidence of penicillin resistant (stippled) and streptomycin resistant (hatched) strains of *Staph pyogenes*

RESISTANCE TO PENICILLIN AND TO STREPTOMYCIN

603 strains of *Staph pyogenes* obtained from 513 inpatients and 90 outpatients were examined for sensitivity to penicillin and streptomycin with the following results

Antibiotic resistance	*No of patients and % of total*	
	Inpatients	*Outpatients*
Penicillin sensitive	239 (*46 6%*)	68 (*75 4%*)
Penicillin resistant	274 (*53 4%*)	22 (*24 6%*)
Streptomycin-sensitive	441 (*86 0%*)	89 (*98 9%*)
Streptomycin resistant	72 (*14 9%*)	1 (*1 1%*)

Penicillin

Some of the 22 (24 6%) outpatients penicillin resistant strains were isolated from patients who had been treated with penicillin, and we do not consider that the incidence of penicillin resistant strains in the general population is 24 6% The incidence of 53 4% inpatients penicillin resistant strains cannot be directly compared with the incidence obtained by Rountree and Thomson (1949) in both inpatients and outpatients If, however, the figures for both types of patients in the present series are combined, the incidence becomes 49%, which does not significantly differ from 47% found in the previous series We therefore conclude that there has been no increase in the incidence of penicillin resistant strains in this hospital during the period under review

Streptomycin

All the streptomycin resistant strains examined were also penicillin resistant From only one outpatient was a streptomycin resistant strain isolated, this was obtained after local streptomycin therapy of a varicose ulcer and was of the same phage type as the previously isolated sensitive strain

From 72 (14%) of the 513 inpatients streptomycin resistant strains were isolated The accompanying figure shows the monthly incidence of penicillin resistant and streptomycin resistant strains expressed as percentages of the total number of strains of *Staph pyogenes* examined each month The figure shows clearly the increase month by month in the incidence of strains resistant to streptomycin There were no such strains isolated in April and May, 1949, but thereafter the figures rose from 2 strains out of 52 examined in June until 13 of 33 strains examined in January were streptomycin resistant

The streptomycin resistant strains were obtained from various sources, including sputum, urine, blood, and pleural fluids, but most of them came from clean surgical wounds cross infected in hospital In some of these patients streptomycin resistance developed after streptomycin therapy given when the infecting organism was found to be penicillin resistant, but there were many cases in which the organism was streptomycin resistant on first isolation

Dust collecting air surfaces of alveolar phagocytes

The alveolar phagocyte may have one, two, three, or even four functional air faces or particle receptors (figs 1 and 2) These vary in area Often one is quite extensive, the others being relatively small Under routine conditions of life these are usually flat or concave, conforming to the contour of the alveolar wall They are often spread like thin omenta over adjoining capillaries (Bargmann 1936) They arrest dust particles, which are engulfed and segregated in clumps in the underlying cytoplasm This mechanism is the normal one for dealing with particulate matter which gains entry to the alveolar air spaces So far as can be learnt from ordinary sections, these plaques cover a relatively small part of the alveolar wall Particles falling on other regions (the bare areas and the air surfaces of the alveolar granulocytes) normally find their way quickly to the plaques by a mechanism that is not understood The thin edges of the plaques have been mistaken for respiratory "squames" by some workers

Origin

The alveolar dust cell is regarded as of endodermal origin (Carleton 1934) and as being a sister of the granular cell of the alveolar wall A dust containing mural phagocyte and an alveolar granular cell may be found side by side in a relation like that of adjoining epithelial cells, and separated by what seems to be a single cell membrane Under a form of biodynamics, certain cells are differentiated in the normal course of life as mural phagocytes, while other residual epithelial cells of the alveolar wall, which are regarded as more primitive, remain as granular cells These latter cells are notable for their content of special granules (Macklin 1947) In usual conditions in mice one finds mainly well differentiated cells of these two types in the alveolar wall, and but few cells which could be regarded as intermediate in type

Mitochondria

The mitochondria are scarce or absent in mural phagocytes and diminish with the densification of the cytoplasm, which apparently is a concomitant of ageing Large spheroids were noted, suggesting a fusion of smaller ones

Gash irrigation results

When fresh collapsed mouse lung is slashed through a drop of physiological salt solution and the part drained on to a slide, liberated dust cells are recovered, together with cells of intermediate type, having granules as well as dust grains A few elements, called pure foam cells, are also seen, and these are regarded as released alveolar granular cells (Macklin 1949)

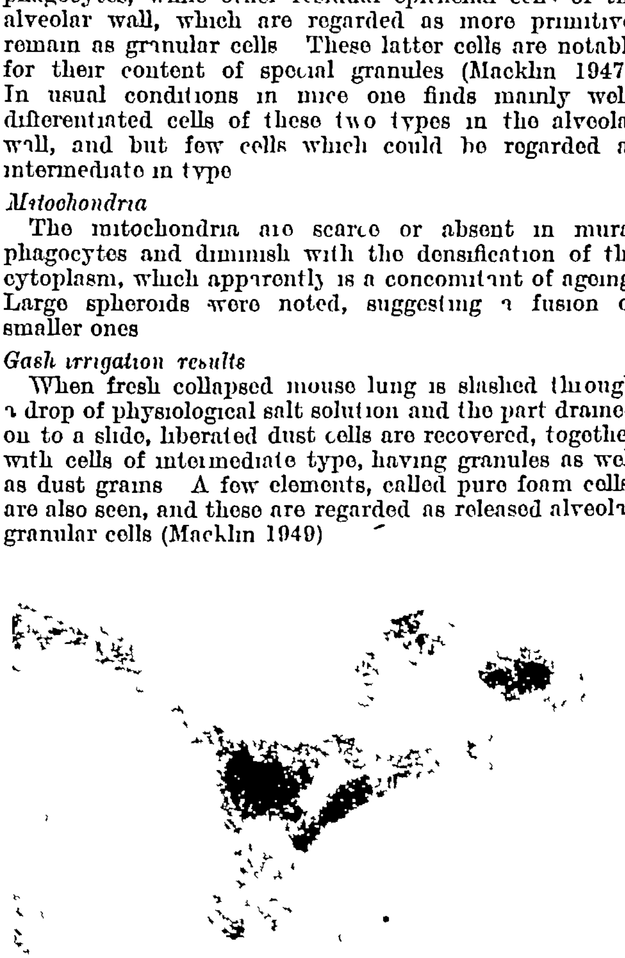


Fig 3—Photomicrograph of a mouse mural phagocyte which was exposed to an hour's vital dusting with carmine powder and fixed by block immersion of the unopened thorax an hour after the end of dusting Two air surfaces are visible The cytoplasm is crowded with carmine grains No carmine grains are seen on the alveolar air surfaces elsewhere. (Harris hæmatoxylin, Orange G ; × 1700)

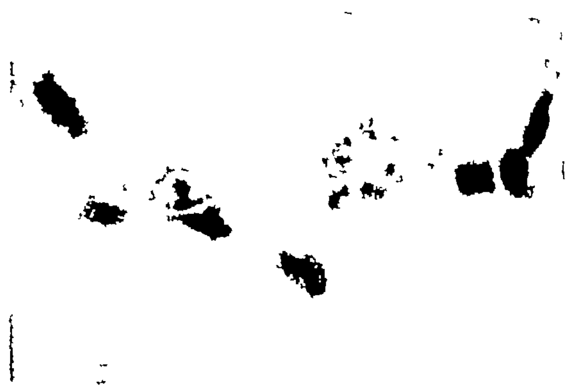

Fig 4—Photomicrograph of one of the rare instances in this mouse lung of a phagocyte which has become free from the alveolar wall (Harris hæmatoxylin, Orange G ; × 1700)

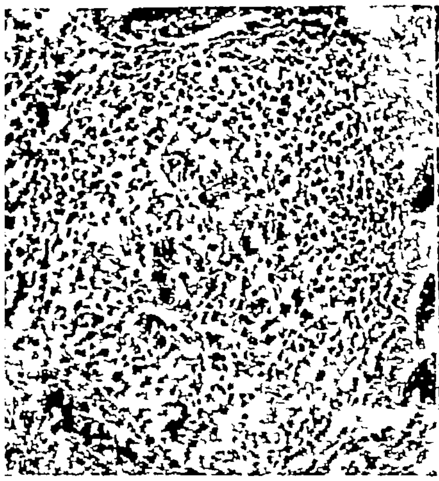
Carmine dusting experiments

One hour after the cessation of exposure of the atropinised mouse to an hour's dusting with carmine powder, the lungs, fixed by immersion of the flayed unopened thorax in Regaud's fluid, show almost all the carmine grains within the wall phagocytes (fig 3) The almost complete clearing of the relatively large areas of alveolar wall, in which no extensions of the mural phagocyte appear, is remarkable What few grains remain are almost all in small clumps Almost 100% of the phagocytes, by actual count, are inserted into the alveolar walls These varied greatly in carmine content, some (called carminophages) were packed with red granules and were very conspicuous, while others, which seemed to contain more black particles of ordinary dust, had taken in lesser numbers of red particles It was rare to find a free carmine containing cell at this stage (fig 4) If however, a week is allowed to elapse after an hour's dusting of the atropinised mouse with carmine powder, the picture is very different Now, by actual count, 65% of the alveolar phagocytes are free, and only 35% are fixed in the wall, and these bulge prominently into the alveolar space and do not show the flattened and extended plaques characteristic of the usual, unstimulated, condition This evidence suggests that the phagocyte may carry on its functions under these conditions while free It may even return to a pore, using it as a "filling station" (a term used in Canada for a source of gasoline for automobiles needing refuelling) because of the accessibility of the capillaries It may be that such a cell may move about the wall and insert a process or processes into one or more pores from time to time as the emergency demands, for food is available nowhere else This evidence, too, shows that the alveolar phagocytes may remain a week or more apparently at work, without being evacuated At this stage there were fewer phagocytes, made conspicuous by close packing of the granules, than in the one hour stage, and this suggests that the well laden phagocytes have departed Stimulation such as this causes the phagocytes to swell and become more compact, the flanges being drawn in and merged with the general cytoplasm

Replacement

The source of alveolar phagocytes has been well debated for many years In the usual course of life the spent and dislodged mural phagocytes must be replaced It is assumed that the loss is made good from sister cells remaining in the walls Perhaps recruits can find their way to vacated emplacements (pores or sockets) in the walls from other loci, and therein establish themselves In the healthy lung there seems to be no diminution in number of alveolar phagocytes with age The replenishment of the supply of alveolar phagocytes after conditions of special stimulation, as in the pneumonias, cannot be here considered



1—A single tuberculous focus in the endometrium (× 160)

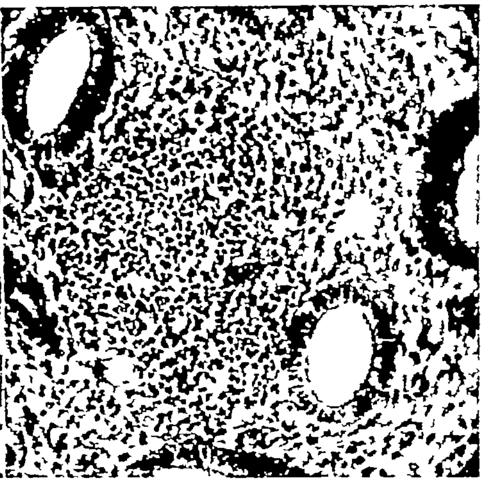


Fig 2—Lymphoid aggregate in the stroma of normal endometrium (× 160)

itions, but these normal structures differ from the ercles in the uniformity of their cells and the regularity their grouping It is presumed that the tubercle cilli lodge in the lymphoid areas of the stroma as they in other organs Thus the lesion is often seen close a gland, and as it enlarges it pushes into and finally rsts into the gland lumen Essentially the endometrial ercle comprises a central zone of endothelioid cells, th prominent eosinophil cytoplasm, surrounded by a riable zone of lymphocytes and plasma cells When e lesion bursts into the lumen, lymphocytes and other lammatory cells will be found within the lumen me of the epithelioid cells may attempt to form int cells, but giant-cells do not constitute tuberculosis, d tuberculosis is frequently diagnosed without them ie periodic shedding of the endometrium cuts short e formation of mature tubercles

Most often these circumscribed lesions are the only normal feature in the endometrium, but there may infiltrations of inflammatory cells in the stroma, th or without the focal lesions Where a section ows these infiltrations, and there is no other demon rable cause for the inflammatory response (e g, retained oducts of conception), it is probably wise to suspect berculosis Unlike normal lymphoid aggregates, such flammatory cells appear diffusely in the stroma

There are other granulomas—though more particularly the fallopian tube—which can be confused with berculosis These include actinomycosis and those ie to helminth infestation, and to oily substances, iabsorbed sutures, talc, and other foreign bodies hese may be distinguished either on clinical evidence, by appropriate staining methods, or by studying eir appearance under polarised light Where bacterio gical confirmation is possible, the exclusion of these ternatives is less important

The aim of the bacteriological investigation is to olate *Mycobacterium tuberculosis* by culture or animal oculation or both, and to submit for typing each strain tained Identification of the organism establishes the agnosis, and it can be tested for drug sensitivity revious work on the typing of strains obtained from ynæcological cases has been scanty and difficult to aluate

Cultivation is possible on a variety of media

First the pieces of endometrium must be converted into a rm suitable for inoculation and this may be done by inding with sterilised quartz sand in a sterile pestle and ortar A loopful (or several) of the ground up material planted on one or more slopes of Dorset egg and Löwenstein ensen media A fluid medium is also used Cultures are xamined at ten days and weekly up to two months

Guineapig inoculation is usually performed using treated material The treatment may be as given above, or one of the many chemical methods may be used Chemically treated material is often regarded as more suitable for culture and inoculation To cover up risks of bacterial contamination, both forms of treated material may be used for culture and for animal inoculation In our experience a simpler method is giving reliable results

Through a small incision in the thigh of the guineapig, the untreated material is placed in the muscles, and the skin is closed with one or two sutures The operation requires a short anæsthetic, but the time taken from the curettage to its completion need be only a few minutes Provided the material is placed deeply, the wound heals perfectly in five or six days The stitch either falls out or is removed by the guineapig Smears are taken from the regional and lumbar lymph nodes and the spleen, and stained for tubercle bacilli The organism is further inoculated on to culture media as described above

There are other methods for the detection of tubercle bacilli in the endometrium, but we have not used them The Ziehl Neelsen technique, which entails much tedious bench work, gives inferior results, and probably (though we have no experience of it) this is also true of fluorescence microscopy of the endometrium (Clegg and Foster Carter 1946, Browning and Mackie 1949) The vaginal discharges, particularly during menstruation, may be searched for organisms (Halbrecht 1947), but this method is not universally applicable

RESULTS

The main object of this paper is to emphasise the value of adequate investigation when judging the results of chemotherapy None of our treated cases can be included in this report, for only preliminary tests have been completed The results of pre treatment investigations of 24 patients can, however, be described

In 18 cases endometrial tuberculosis was diagnosed both histologically and by the method of guineapig inoculation described above In 4 cases diagnosed histologically, animal inoculation gave negative results In 2 of these tuberculous endometritis was present but the material examined was from the tubes only In the other 2 the disease was seen in the tube or ovary, but not in the endometrium, and only one animal test was performed in each case—on material obtained at operation Perhaps a repetition of the test would have given bacteriological confirmation, this has been our experience in 3 of the 18 cases already mentioned Finally there are 2 patients whose investigation has so far given discordant results

In certain cases positive findings (histological and bacteriological) have been followed by double negative findings though the patient had not had any treatment In another case a test after a course of streptomycin gave a positive guineapig result with negative histology (One sample of endometrium, divided, was used for the test)

A few patients with pulmonary tuberculosis have been investigated but with consistently negative findings Negative results have also been returned on a number of occasions in which endometrial tuberculosis has been suggested on clinical grounds These two negative groups comprise about 30 cases

PHAGE TYPES OF STREPTOMYCIN RESISTANT STRAINS

It is apparent that we are observing with the streptomycin resistant strains the same type of increase in incidence as has already taken place with penicillin resistant strains, and it becomes of interest to consider what phage types are involved in this development of streptomycin resistance The phage types differentiated among 70 streptomycin resistant strains were as follows

Phage type	*No of strains*
31B	21
47	17
47/31B	11
7	4
7 other types	14
Not typable	3

In contrast to the scheme of classification adopted by Barber and Whitehead (1949) we have preferred to differentiate between types that are fairly closely related —e g , 7, 31B, 47, and 47/31B—rather than to include all these strains in one group, 6/7/47 Though there is no doubt that there is a close genetic relationship between these strains (Smith 1948), the differences observed in their "pattern reactions" with the series of phages used have remained constant during the period under consideration Further, successive cultures from the same patient have yielded strains with identical "pattern reactions" , any change in the phage reactions has been regarded as evidence of cross infection with another strain and has usually been correlated with other observable changes in colony appearance This differentiation of closely related types has allowed us to follow the rising incidence of types 47 and 47/31B, which were infrequently found in the hospital during the previous period from October, 1948, to March, 1949

The three types 31B, 47, and 47/31B account for 49 (70%) of the streptomycin resistant strains typed 4 strains of type 7 were recognised , of the remaining 17 strains 3 were not typable and the other 14 belonged to 7 other phage types These 14 strains, however, with 2 exceptions, belonged to types which can be included in the 6/7/47 group

The increased incidence in this hospital of strains of *Staph pyogenes* insensitive to both penicillin and streptomycin is therefore due to the propagation in the hospital environment of strains belonging to only a few phage types

One fact of obvious interest is that the strains of type 7 and 31B are those which were predominant in the hospital as penicillin resistant streptomycin sensitive strains before the introduction of extensive streptomycin therapy The emergence of streptomycin resistant variants during streptomycin therapy of patients cross infected with these strains and with strains of type 47 has been previously observed (Barbour 1950) After these streptomycin resistant strains had appeared in patients they were subsequently isolated from the noses of nurses and from the dust and air of the wards Examination of 90 colonies of *Staph pyogenes* obtained on blood agar plates used for taking a series of air samples in surgical wards during February, 1950, showed that 75 colonies were penicillin resistant and 58 resistant to both penicillin and streptomycin All the doubly resistant colonies belonged to types 31B, 47, or 47/31B

It might be concluded from this evidence that antibiotic resistant staphylococci of group 6/7/47 predominate in hospitals because, as antibiotic sensitive strains, they were already well established in the hospital environment when penicillin and streptomycin were introduced On the other hand, it has been suggested (Barber and Whitehead 1949) that strains of this group are genetically less stable than those of other phage groups and so give rise to resistant mutants more rapidly In our opinion the data presented here do not allow us to distinguish between these two hypotheses, and it seems possible that both mechanisms may be operating

SUMMARY

Of the 603 strains of *Staph pyogenes* isolated from inpatients and outpatients between April, 1949, and April, 1950, and examined for sensitivity to penicillin and streptomycin and for phage type, 274 (53 4%) from 513 inpatients yielded penicillin resistant strains, compared with 22 (24 6%) from 90 outpatients

Strains resistant to both penicillin and streptomycin were obtained from 72 (14%) of 513 inpatients compared with 1 of 90 outpatients This incidence of 14% was significantly higher than the 3 5% obtained with 199 patients examined in the preceding six months (Rountree and Thomson 1949)

At least 65 of these doubly resistant strains belonged to phage types of the genetically related group 6/7/47

This work was supported in part by a grant from the Australian National Health and Medical Research Council We wish to thank Mr G Barr and Miss V Sife for their excellent technical assistance

TUBERCULOSIS OF THE ENDOMETRIUM

INVESTIGATION AND TREATMENT

MAGNUS HAINES
M D Lond
DIRECTOR OF PATHOLOGY, CHELSEA HOSPITAL FOR WOMEN, LONDON

With the technical assistance of J W LAW, A I M L T

IN the earlier literature references to unsuspected uterine tuberculosis are few Comyns Berkeley (1935) found unsuspected genital tuberculosis in 62 of 795 (7 7%) females dying of pulmonary tuberculosis, the body of the uterus being affected in 18 (2 3%)

Over the past ten years several authors (Schockaert and Ferin 1939, Sutherland 1943, Halbrecht 1946, O'Brien and Lawlor 1947) have reported finding tuberculosis in the endometrium of women who were symptomless The incidence has been unexpectedly high 5·3% (Sharman 1947) and 6% (Schockaert and Ferin 1945) These reports, however, refer to women seeking advice at fertility clinics—a selected group In the general population of women under hospital care the incidence is estimated at about 1% (Sutherland 1943) The subject in general has been reviewed by Sutherland (1943, 1950) and Bamforth (1950)

Since 1946 we have been investigating a small group of similar cases, and recently we have undertaken controlled treatment by chemotherapy

INVESTIGATION

Whenever tuberculous infection is found in a specimen of endometrium, obtained either for examination or during full curettage, the patient is asked to return for a repeat biopsy This should be within the seven days preceding an expected period, at which time the volume of the specimen should be greatest On this second examination the material is divided into two portions —one for histology and one for bacteriology

Histologically tuberculosis in the endometrium resembles tuberculosis in other tissues , but the more advanced stages (caseation, fibrosis, and calcification) are rarely seen The lesion (fig 1) is typically a focal one, situated about midway in the endometrium It is in the stroma but adjacent to glands The normal endometrium has lymphoid aggregates (fig 2) in corresponding sympathetic fibres from the 2nd, 3rd, and 4th sympathetic ganglia are inextricably mixed up with the plexus, and one cannot be certain of having removed them unless the whole plexus is dissected out; not only is this a time-consuming and sanguinary operation, but also it is impossible to be sure when the task is completed because the plexus and the areolar tissue appear so much alike.

CASE RECORDS

Case 1.—A man, aged 44, had enjoyed excellent health up to the age of 40. At that time he married, but the union was a failure, and he started to have mild attacks of asthma, which disappeared when he obtained a divorce. Good health followed until 6 weeks after his second marriage, nearly 2 years ago. The asthma then began in earnest, although his second wife was a paragon. Time after time he relapsed with severe attacks always necessitating hospital treatment and completely incapacitating him for work.

Investigations into possible allergy made him worse. He was found to be sensitive to moulds, but desensitisation did not help, and he developed a mould mania: he pulled up the boards of his house in his obsessional witch hunt, and when in hospital, much to the matron's annoyance, he found some penicillium growing in his bed locker. He was examined psychiatrically, and it was thought that the uncertainty of the reaction of his children to their new mother might explain his trouble. It may have been so, but the knowledge of it did not make the slightest difference to the patient. Between attacks he was perfectly well, and there was no evidence of any permanent damage to his lungs.

He was considered suitable for operation, and vagal resection was done when he was asthma free in March, 1950, nineteen days separating the operations on the two sides.

The response was dramatic. He put on weight, lost his asthma, and left hospital a new man. He went back to work for 4 happy months, after which he returned to hospital with a relapse. His attacks before and after operation seemed to me to be exactly the same, but he is again at work and he regards the operation as miraculous. He still thinks of his 15 weeks' freedom, says that his present relapses have not been nearly so severe as his previous attacks, and continually advises fellow sufferers to seek operation.

Case 2.—A married woman, aged 62, had begun to have asthma about 12 years ago; at that time her husband won some money and immediately took to drink and became unmanageable. Her daughter, now married, started attacks at the same time, and it is alleged that the wheeziness in one precipitated it in the other. Attacks in the patient appeared to coincide with her husband's bouts of drinking. No allergic factors were discovered, but she stated that she sometimes had dermatitis with the asthma. This latterly had been complicated by bronchitis, purulent and occasionally bloodstained sputum being coughed up. Her spasms were of appalling severity, and in them she was often unconscious and always incontinent. Heart-failure had been a complication early this year. In between the severe attacks she was always giving herself injections of adrenaline. Vagal resection was advised in view of the failure of all the usual measures, and the left side was done on July 27, 1950. The right side was done on Aug. 22.

The result to date has been remarkable. She has been entirely free from asthma since the first operation and denies having had the slightest trace of a wheeze. She has thrown away her inhaler and all her drugs, is living an entirely normal life, and says she has never been so well for 12 years. Her domestic troubles, though still present, no longer appear to worry her now that she is free from asthma.

Case 3.—A girl, aged 21, had had eczema and asthma from the age of 4 years. "Since the bombing" the asthma had been progressively worse, and from the time that I came to know her 2 years ago she had been in and out of hospital a dozen times or more. Why she relapsed nobody knew. She was a flat inhibited dull sort of girl, unlike the usual asthmatic type, and we all rather felt that she did not make much effort to get better, though her attacks were so very violent. She was found by skin tests to be sensitive to house-dust, horsehair, feathers, moulds, and fish, but specific desensitisation, and later 'Lertigon,' made no improvement. Yet she, too, was well in between the attacks, with no evidence of chronic infection or emphysema. For this reason I advised vagal resection, which was done in June, 1950. For four months she improved and had no attacks, but she remained somewhat wheezy and was taking half a tablet of 'Neo-Epinine' daily. She also complained of cough and shortness of breath. She relapsed in November with a typical attack, but she too insisted that it was not nearly so severe as those before operation.

Case 4.—A single woman, aged 31, had had chest trouble of one kind and another since infancy. She had pneumonia at the age of 4, pleurisy at the age of 7, and multiple attacks of bronchitis during adolescence. True asthma started about the age of 21 and continued from that time with increasing severity. In January, 1950, associated with a bad attack, she had a right-sided spontaneous pneumothorax. A second pneumothorax (also right-sided) developed in March with a further attack of asthma. Physical examination at the end of April showed her to have severe emphysema and chronic bronchitis, and at that time she was also dyspnœic and wheezy.

Vagal resection was performed on May 6 and 20, 1950, and in addition it was considered that the bilateral thoracotomy would fix the lungs by pleural adhesions to prevent any further pneumothoraces. The immediate postoperative course was good; her asthma disappeared and she went home much improved. This improvement was maintained for $2^1/_2$ months, but she was never strong enough to get back to her work as a secretary. She relapsed in mid-August with a severe attack of asthma complicated by bronchitis. With heavy sedation she gradually improved sufficiently to go to the South of England. There she relapsed again and has required a further period in hospital since coming home. Her doctor tells me that, although her attacks have been severe, she has never been so acutely ill as before the operation.

Case 5.—A boy, aged 15, had had asthma prurigo syndrome since the age of 3 years, the eczema and asthma often alternating. Precipitating factors known to the patient were certain fruits, fish, grass in May and June, and house-dust. During the past few years the asthmatic attacks had been getting progressively severe in spite of desensitising injections to the appropriate allergens. In between the attacks he was reasonably well and played games at school. He was alert and bright mentally, with a very good visual and auditory memory. Because of the increasing severity and progressive lessening of free intervals, vagal resection was advised, and the operations were performed in January, 1950. He stood them well and remained free from asthma while in hospital. He relapsed on the doorstep the moment he arrived home. For the first 3 months after operation the asthma was less severe, attacks lasting $^1/_2$–1 day and occurring at intervals of 7–10 days. Between June and August they became slightly more infrequent, occurring at intervals of 12–14 days. In August, while free from attacks, the patient began to have precordial pain and tachycardia on exertion. These symptoms persist. His asthma has relapsed badly. He is now getting attacks every day. He is losing weight, not growing, and his condition is no better and perhaps worse than before operation.

Case 6.—A girl, aged 18. She had had attacks of asthma, worse in the summer, since the age of 7, and in the past year the attacks had been extremely severe and very frequent. She had been found to be sensitive to pollens, mixed moulds, and house-dust, but desensitisation to these had not materially affected her. On the psychological side it was thought that there might be some instability of background, since her father and mother were separated and she was looked after by her grandmother. Vagal resection was decided on, and the right side was done on Aug. 29, 1950. The patient stood the operation well but developed a cold a fortnight later; it was therefore decided that she should convalesce before the other side was done. I saw her again a fortnight later, when she had been admitted to hospital as an emergency. Her asthma had returned and her condition was exactly the same as before operation. None of us could detect the slightest difference in the spasm of the operated and non-operated sides. The condition cleared quickly and the second side has now been done, but insufficient time has elapsed for assessment.

COMMENT

If one had to hazard a guess at the outcome of any new form of treatment in asthma, one could safely predict that the immediate result would be good but that

TREATMENT

Until recent times no clear views on treatment have been expressed, except for cases in which symptoms and signs have indicated removal of the uterus and/or tubes and ovaries Modern chemotherapy, however, has offered new hopes of cure

The drugs available are streptomycin and *p* amino salicylic acid, *and though the lesions are small and often* few in number, we think it necessary to give a heavy treatment—i e, daily doses for three months of 1 0 g streptomycin and not less than gr 10 *p* aminosalicylic acid Apparent cures should not be accepted as definite until there is presumptive evidence that the patient's disease has been arrested over two or three years

The small size of the endometrial lesion does not mean that the infection can be eradicated easily Though endometrium and fallopian tubes may be involved at the same time, the infection is blood borne and comes from a distant focus The chemotherapeutic attack is on the distant focus as well as on the uterus In the cases reported by others, *and those encountered by us*, there has often been a history of tuberculous disease for ten or fifteen years or more

Accordingly, frequent biopsies of the endometrium are inadvisable, and after a course of treatment it seems best to wait for three months, repeating the examination two or three times per annum subsequently The material should always be examined both histologically and bacteriologically A negative histological result while waiting (two months) for the bacteriological finding can raise false hopes

DISCUSSION

The silent tuberculous lesion of the endometrium is not as rare as has been supposed and it can be recognised by methods which are easy to follow In 22 of our cases the diagnosis was unequivocal and absolute bacteriological confirmation was obtained in 18 We have not yet proceeded with the typing of strains of *Myco tuberculosis* isolated, but this is clearly desirable We attach great importance to reducing the number of post chemotherapy biopsies and curettages and increasing the intervals between them (Haines 1950) Cure cannot reasonably be presumed because the endometrium has not developed a new tuberculous focus in the month —or even the three months—following treatment, for pelvic tuberculosis is a blood borne disease and the focal point must often be outside the gynæcological field Caution in judging the effects of streptomycin treatment is as necessary here as in other forms of tuberculosis

SUMMARY

Of 24 cases of tuberculous endometritis, recognised histologically, the diagnosis was confirmed bacteriologically in 18 and 2 are still under review Examination of 30 other patients gave negative results

The need for care in judging the effects of treatment is emphasised Repeated biopsies are necessary, but should not be frequent

We wish to express our thanks to the clinical staff of Chelsea Hospital for Women for their help in following these cases, and to Mr H J Turner for the photography

BRONCHIAL ASTHMA TREATED BY BILATERAL RESECTION OF THE VAGUS*

A REPORT OF SIX CASES

C A Clarke
M D Camb, F R C P
ASSISTANT PHYSICIAN, ROYAL LIVERPOOL UNITED HOSPITAL
(DAVID LEWIS NORTHERN BRANCH)

BRONCHIAL asthma, *as every honest man knows*, is incurable Children may grow out of it, and adults have long periods of freedom, but the fact remains that *an asthmatic is always a potential* wheezer, and no particular drug or method of treatment is a specific against relapse You have only to look at the case records of any asthma clinic to see the natural history of the disease—relapse and remission—unfolding itself

The worst cases are a challenge to medical science, and where all else has failed, operations have been performed on the autonomic nervous system with a view to isolating the lungs from external influences

Miscall and Rovenstine (1943) and Carr and Chandler (1948) reported success from bilateral injection or excision of sympathetic ganglia Klassen et al (1950) obtained equivocal results in three patients treated by *vagus resection and showed by* bronchography that bronchospasm was still present Blades et al (1950) reported "cure" or improvement in twenty two out of thirty eight patients treated by vagus resection, the operation in some cases being confined to one side only Earlier, Rienhoff and Gay (1938) had attempted complete denervation by bilateral resection of the posterior pulmonary plexus, and they reviewed twenty one cases between 4 and 8 years after operation (Gay and Rienhoff 1942) There had been *nine* deaths, seven in the immediate postoperative period Four cases were entirely unimproved The successes numbered eight—three "100%," one "75%," and four "50%"—but one of the last died from heart failure 7 months after operation There was no correlation between the ages of the patients and the success, or otherwise, of the operation The operators were impressed by the fact that they were quite unable to forecast which cases were likely to do well and which badly, their only criterion for operation was failure of medical treatment, and they suggest that the best cases may be those in which one has no clue to the exciting cause They would exclude all cases palpably associated with any known cause—be it psychoneurotic, infective, or allergic They make two points of interest about their operation (1) where asthma occurred between the two operations it tended to be unilateral and confined to the unoperated side, and (2) it often took several months for the asthma to clear, the attacks gradually becoming less and less severe

The present series was selected for very much the same reasons as Rienhoff and Gay's, but the patients had been, on the whole, less continuously ill.

The operations were done by Mr Ronald Edwards and Mr H V Wingfield, at the Liverpool Chest Surgical Unit, Broadgreen Hospital, the technique being as follows

The chest was opened up via the bed of the displaced 6th or 7th rib The vagus nerve was identified posterior to the lung root, and all branches going to the posterior pulmonary plexus were divided, segments being excised from them The main branch to the anterior plexus was also divided About 3 weeks separated the operations on the two sides.

The procedure resembles that of Rienhoff and Gay, but they would criticise us for leaving the sympathetic connections Mr Edwards states, however, that the

---

* Abridged from a paper read to the British Association of Allergists at York on Oct. 7, 1950

Necropsy Findings—The liver was grossly enlarged and diffusely and densely studded with tumour nodules from a few millimetres to a few inches in diameter Secondary deposits were found in the right fourth and fifth ribs and in the body of the sternum. The lungs were congested and œdematous, the kidneys swollen and deeply congested. The pancreas was somewhat adherent to the liver, it appeared normal in all respects and in all parts except in the substance of the mid body, where fleshy nodules could be felt No extrahepatic primary growth was found, and a primary intrahepatic carcinoma was diagnosed

Histology—Sections of the liver showed a hepatoma of multifocal origin. In the kidneys epithelial damage to both sets of convoluted tubules was severe, and the lumina contained much eosinophilic granular debris and some detached cells Congestion was well marked, and most glomeruli showed a similar debris, with hæmorrhage in the capsular spaces of some The cytological findings in the pancreas are presented below with the account of the effects of alloxan Here suffice it to say that numerous sections of the nodules in the body of the pancreas showed these to consist of simple hæmolymph glands

Biochemistry—The results of relevant tests were as follows

Date	*Investigation*	*Results and comments*
Dec 5 1949	Urea level of ascitic fluid	12·6 mg per 100 ml
10 1949	Blood urea	61 mg per 100 ml (36 hours after intravenous alloxan 20 g)
Nov 14 1949	Blood lipoids	Cholesterol 173 mg per 100 ml total lipoids (Mata) 1160 mg per 100 ml (normal = 450–550 mg) blood fatty acids = 987 mg per 100 ml (normal = 310–360 mg)
17, 1949	Serum-citric acid	53 3 mg per 100 ml (5 controls = 1 66 2 15 3·6 2 9 and 2 4 mg)
17 1949	Blood pyruvic acid	3 72 mg per 100 ml (normal about 1 mg)
17 1949	Urinary citric acid	133 mg per 100 ml.≡1 86 g per 24 hr (6 male controls = 30 27 5 35 75 44 22 5 and 19 2 mg)
17 1949	Urinary pyruvic acid	10 0 mg per 100 ml ≡ 0 14 g per 24 hr (control = 1 24 mg per 100 ml.)
20 1949	Urinary citric acid	71 4 mg per 100 ml ≡ 1 16 g per 24 hr
20 1949	Urinary pyruvic acid	6 56 mg per 100 ml ≡ 0 11 g per 24 hr
Dec 1 1949	Urinary citric acid	77 5 mg per 100 ml ≡ 1·04 g per 24 hr
1 1949	Urinary pyruvic acid	3 8 mg per 100 ml ≡ 51 1 mg per 24 hr
8, 1949	Plasma citric acid	19 8 mg per 100 ml
8 1949	Blood pyruvic acid	2 3 mg per 100 ml

At no time were any ketone bodies found in the urine on repeated routine tests Citric acid was determined by the method of Pucher et al (1936), and pyruvic acid by that of Friedemann and Haugen (1943)

DISCUSSION

It is considered that the condition was one of organic hyperinsulinism due primarily to hypertrophy and hyperplasia of the islets of Langerhans, and later complicated and exacerbated by the development of a primary liver-cell carcinoma

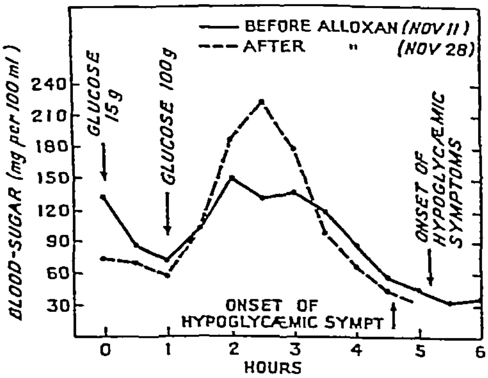

Fig 2—Glucose-tolerance curves before and after alloxan 8 3 g by mouth.

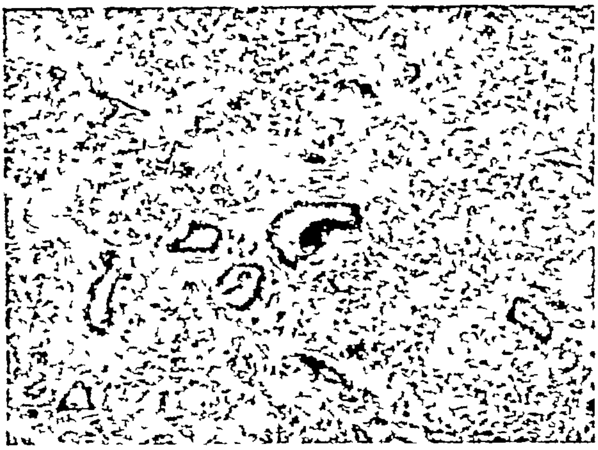

Fig 3—Pancreas showing abundant islet tissue in places associated with small ducts (Hæmatoxylin and eosin, × 95)

Clinical Evidence

In the present instance Whipple's three criteria (Graham and Oakley 1950) of organic hyperinsulinism are satisfied (1) the attacks occurred when the patient was fasting, (2) the attacks were relieved by glucose given without the patient's knowledge—i e, when he was in coma—and (3) the blood sugar level was below 50 mg per 100 ml. during the attacks (fig 2) Conn's (1947) criterion that severe hypoglycæmia is always precipitated by a short fast was also satisfied.

Owing to the rapidly increasing severity and frequency of the attacks Conn's (1940) standard dietary preparation for the glucose tolerance tests could not be used, and the tests had to be modified Glucose (100 g) had to be given at least once during the night preceding the test At 7 A.M 50 g of glucose was given, this was followed by a light breakfast at 8 A.M The tests were begun at 9 A.M with 15 g of glucose followed by 100 g at 10 A M The two curves (fig 2) require little comment Other workers—e g, Kane (1947)—have described also attacks of acute abdominal pain associated with hyperinsulinism

Although we have no definite clinical evidence of the effect of alloxan on the hypoglycæmia, the attacks decreased in frequency and severity during the twenty-four hours after the patient's discharge from hospital The nature and significance of his terminal coma are uncertain After 8 g of alloxan by mouth, the second glucose tolerance test showed a suggestive peak at $2^1/_2$ hours Lukens (1948) records the experimental production of diabetes by oral alloxan, though it is generally agreed that oral administration is ineffective

The toxic effects of alloxan (which have been noted by others) include thrombophlebitis, rigors, vomiting, and tetany (Graham and Oakley 1950) Brunschwig et al. (1944) observed restlessness, cyanosis, perspiration, dyspnœa, vomiting, and severe hæmolytic anæmia with jaundice Conn and Hinerman (1948) remark on the light red colour of the urine after alloxan and independent of hæmaturia, and attribute it to a reduction product This was also seen by us Conn and Hinerman (1948) and Brunschwig et al (1944) state that the blood-urea level did not rise after the administration of alloxan, though the transitory occurrence of casts, red cells, and a trace of albumin in the urine were seen In the present case, thirty six hours after the intravenous injection of 20 g of alloxan the blood urea level rose to 61 mg per 100 ml., and hæmaturia and oliguria were followed by anuria a relapse would follow That this has generally happened in the present small series is clear, though whether the remissions have been due to psychological causes or to some non specific effect of the operation is not known The results up to now must be regarded as poor, and it is clear that it is possible to have typical bronchial asthma after resection of the vagus nerves to the lungs We feel, however, that at any rate no harm has been done, and the procedure seems to be reasonably safe in Mr Edwards's hands It is just possible, too, that in some of the cases we are witnessing the gradual post operative improvement noted by Rienhoff and Gay This, and the striking result in case 2, leads us to think that there is just enough evidence to warrant the operation in intractable cases We agree, however, with Rienhoff and Gay that there is no indication that any particular type of patient will benefit, the only criterion being "failure of medical treatment"

SUMMARY

Six patients with intractable bronchial asthma underwent bilateral resection of the vagus The results on the whole were disappointing, but it is felt that there is a case for further observations

My thanks are due to Dr R Coope, Dr L Findlay, and Dr W S Sutton for permission to report their cases

ADDENDUM

Four months after this article was written a follow up showed

Case 1 —Several relapses Condition similar to that before operation

Case 2 —Remained entirely well

Case 3 —No further relapses, occasional wheeziness Distinct general improvement

Case 4 —No further relapses Slow improvement and back at work Wheezy bouts occasionally, relieved by aminophylline or inhaler

Case 5 —Marked improvement since tonsillectomy in October, 1950

Case 6 —No relapse since second operation Married

ORGANIC HYPERINSULINISM TREATED WITH ALLOXAN

W S L GILCHRIST
M D Belf, M R C P
CONSULTANT PHYSICIAN

M J G LYNCH
M B N U I, M R C P
PATHOLOGIST

FARNBOROUGH HOSPITAL, FARNBOROUGH, KENT

THIS case is considered worthy of publication because of the two factors in the ætiology and the results of treatment with alloxan

CASE RECORD

The patient, first seen in 1949, was a man aged 36 working as overseer at the General Post Office His illness had begun in childhood, for in 1918 he had griping pains in both sides of the lower abdomen, radiating into the left side of the chest At first the pains would come on after every meal on two successive days, with no further pain for about a year Early in 1949, however, the attacks grew more frequent and severe, lasting for two hours (The appetite remained good) He took to his bed on Sept 6, 1949, because of increasing prostration and night sweats, which wakened him at night The attacks, from being intermittent, became regular, occurring each midnight, occasionally he had a further attack at 6 A M At this stage his wife sought the advice of a pharmacist, who suggested the use of glucose Taken at bedtime this prevented most of the midnight attacks, but he continued to have occasional attacks at 6 A M Attacks were promptly relieved by glucose He had lost half a stone in weight in the year preceding his admission to hospital on Oct 13, 1949 A feature of note in his past history was that about 1937 he had an attack of infective hepatitis

On examination he was thin but not emaciated The liver edge was palpable in the right midclavicular line at the level of the umbilicus, it was round, firm, and not tender Two moderate sized nodules were palpable on the edge of the right lobe

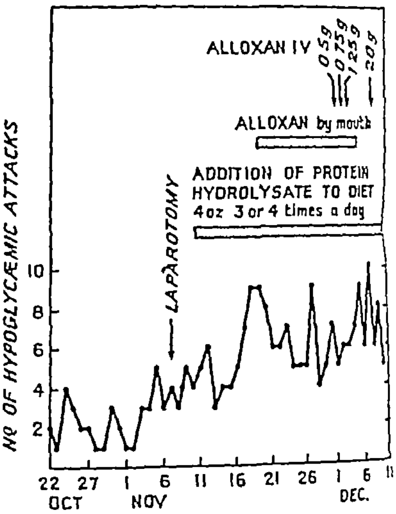

Fig 1—Frequency of hypoglycæmic attacks.

Progress —At 6 A M on Oct 15 he woke and asked for water He then became restless and excited, and struggled violently His recovery was spontaneous At 5 15 A M on Oct 24 he came out in a cold sweat and became irrational, recovered a little, and then suddenly lapsed into coma at 6 30 A.M Two hours later, when seen by the house physician, he was in a deep coma, breathing stertorously, and sweating profusely His pulse was rapid and irregular and his blood pressure 160/70 mm Hg The plantar responses were extensor On being given 15 ml of 50% glucose intravenously he recovered rapidly At this time he was having two or three (hypoglycæmic) attacks each day (fig 1) Usually he would begin to sweat profusely, lapsing rapidly into coma unless given glucose by mouth On other occasions the attacks were more gradual and showed all the features typical of hypoglycæmia.

Diet —On Oct 22 he was put on a 2000-calorie diet, equivalent to 210 g of carbohydrate and 75 g of protein a day Unfortunately his appetite became very capricious and it proved impossible to proceed with proposed observations on a high protein diet He was given 100 g of glucose orally at the beginning of each attack

Operation —On Nov 7, a laparotomy was performed by Mr Cyril Cookson The liver was found to be much enlarged and congested, with large firm whitish nodules on its surface The tail of the pancreas appeared normal, but its head was fused with the liver No evidence of peptic ulceration was found A small piece of liver was taken for histological examination This specimen was unrepresentative and was wrongly taken to be a metastasising islet-cell tumour

Postoperative Course —Shortly afterwards the patient deteriorated steadily and developed ascites The hypoglycæmic attacks increased in frequency and severity The addition of casein hydrolysate to his scanty diet did not affect their occurrence His condition continued to deteriorate steadily and a secondary deposit appeared on the right side of his chest

Alloxan Therapy —From Nov 19 to Dec 5 he had 17 3 g (fig 1)) of alloxan (14 8 g by mouth and 2 5 g intravenously However, the frequency of hypoglycæmic attacks increased On Dec 8 alloxan 20 g was administered in 250 ml of physiological saline solution, together with intravenous penicillin 500,000 units in 45 minutes On Dec 9 there were oliguria, albuminuria, and hæmaturia, followed next day by anuria and a slight icteric tinge in the skin Two very severe hypoglycæmic attacks occurred that afternoon At 7 P M his wife took him home against medical advice His doctor informs us that he had a mild hypoglycæmic attack at midnight on Dec 10 1949, and a more severe attack at 3 next morning At 8 A M he complained of pain in the lumber region Thereafter he lapsed into coma and he died at 4 30 P M on Dec 11, 1949

TUBERCULOSIS OF THE NASOLACRIMAL DUCT

P G KONSTAM
F.R C S.E
LATE ACTING DIRECTOR, CASUALTY SERVICE

M J MEYNELL
M.D , B Sc Sheff , M.R C P , D.P.H.
CLINICAL PATHOLOGIST

THE GENERAL HOSPITAL, BIRMINGHAM

TUBERCULOSIS of the nasolacrimal duct is sufficiently ncommon to be worth recording, particularly if, as e believe, the condition arises primarily in the duct ithout evidence of disease of either the eye or the nose, nd when there is no evidence of tuberculosis elsewhere—e , it is a primary complex The condition can be best escribed as a primary tuberculous "chancre" of the asolacrimal duct

The only English reference found is that of McKenzie 1939), who describes a case secondary to tuberculosis f the turbinate bones, and summarises previous reports

Seifert (1899) stated that tuberculosis of the naso-acrimal duct was always secondary to tuberculosis of he bony walls (very rare and possibly associated with upus), the nose, or the conjunctiva He held that the ommonest route of infection was from the nose So ong as the mucous membrane of the lacrimal sac was ealthy and the lumen of the duct was patent, infection vas unlikely owing to the free flow of secretion As soon s the lower opening was closed, infection might enter rom above in the tears, or more likely from below—e , the nose Seifert mentioned three cases of tuberculous nasolacrimal duct due to primary nasal infection

Work has been done experimentally in rabbits Gourfein (1899) showed that a primary infection of the nasolacrimal duct could be produced two to four months after the introduction of tubercle bacilli into the conjunctival sac He concluded that the lacrimal ducts were not protected by natural secretions

Aurand (1900) described a case in a man, aged 24, who presented with an infection of the lacrimal sac which was followed three years later by tuberculosis of the nose and conjunctiva

CASE RECORD

A boy, aged 14 months, was first seen in the casualty department on Oct 6, 1949 Examination revealed a small indurated nodule with superficial ulceration, the whole the size of a small pea, just beside the right inferior lacrimal canaliculus There was another ulcer about $^1/_4$ in in diameter, flat and dry, on the cheek in the region of the superficial parotid (preauricular) glands The right submandibular glands were visibly enlarged and palpable There was a decided right hemifacial œdema No other abnormalities were detected The child s general condition appeared good

Previous History—In June, 1949, his mother noticed a swelling of his right eye which discharged a small quantity of purulent material Shortly after this she noticed a small swelling over the parotid gland He was taken to a doctor, who treated him with sulphonamides In September the doctor incised the swelling over the parotid Apparently a small quantity of purulent material was obtained and the resultant ulcer never healed properly Three weeks before the boy was brought to the hospital his doctor noticed further swellings in the submandibular region.

Family History—He is an only child His mother, when first seen, denied any family history of tuberculosis All we could do by way of investigating her was to radiograph her chest and estimate her erythrocyte sedimentation rate (E S.R) Radiography showed some consolidation below the apex of the left lung which could very well be tuberculous The E S.R was normal There were no physical signs of tuberculosis of the chest, and the mother refused to have her sputum examined. After a good deal of persuasion we managed to obtain a radiograph of the father s chest which showed calcified spots on the right side—evidence of old fibroid phthisis The father reluctantly admitted having been in a sanatorium for some time with an artificial pneumothorax He refused to indicate when his sputum had last been positive, but hinted that it was not long ago He would not coöperate, and nothing beyond a radiograph could be got from him

Investigation of Patient—The submandibular swelling was aspirated The specimen consisted of mucopus Stained films showed debris with occasional pus cells A few acid-fast and alcohol fast bacilli were present No other organisms were seen Cultures showed no growth after seventy two hours Cultures on Sabouraud s medium remained sterile after fourteen days' incubation at 20–22°C A blood-count showed Hb 76% and white cells 9600 per c.mm (differential count not significantly altered) Radiography showed no obvious abnormality of chest or sinuses Sinus puncture was not attempted Examination of nose, pharynx, and eyes was negative A Mantoux test was strongly positive in a dilution of 1 in 100 000 A biopsy specimen from the edge of the ulcerated area over the parotid lymph gland proved to be skin and subcutaneous tissue The dermis was densely infiltrated by acute and chronic inflammatory cells and many typical tuberculous giant cells, strongly suggesting tuberculosis

Treatment and Progress—A course of streptomycin 0 25 g six hourly was begun on Oct 21, 1949 The child s general condition remained good and at no time did he have pyrexia However, on Nov 7 the fluctuant swelling over the submandibular region was aspirated and more mucopus was removed The child was thenceforth given 'Calciferol' 50,000 units daily in addition to the streptomycin Despite this therapy the swelling increased, so it was excised on Nov 19, 1949 The entire mass of superficial and upper deep cervical glands was removed They had broken down and were in different stages of destruction. Histologically the lymph nodes were almost entirely replaced by large numbers of typically tuberculous follicles Caseation was present All the lymph nodes showed a well defined fibrous tissue reaction Cultures on Lowenstein-Jensen medium and animal inoculation test proved positive for tubercle bacilli The streptomycin sensitivity tests showed a fully sensitive strain of tubercle bacilli No section was made of the original lesion in the nasolacrimal duct, because it was considered unjustifiable Swabs of the nasolacrimal ulcer and of the conjunctiva showed no tubercle bacilli on either microscopy or culture The boy received 31 5 g of streptomycin in four weeks and two days and 800 000 units of calciferol in sixteen days The lesions dried and began to heal with some scarring The hemifacial œdema completely disappeared He was discharged, and it was arranged for him to attend hospital as an outpatient

DISCUSSION

The lesion in the present case is believed to be a primary tuberculous complex because (1) no tuberculosis was found elsewhere, (2) the age was only 14 months, and (3) the regional lymph glands were severely affected, the process going on to caseation

Admittedly there is no history of a negative Mantoux reaction before the onset of this condition, but the evidence on the whole is in favour of such a presumption In addition, we consider this case to be one of primary involvement of an apparently healthy nasolacrimal duct in view of the negative findings in either the nose or the eye

Presumably the original source of infection is the father, who had a history of phthisis and whose sputum had contained tubercle bacilli He seems to have infected both mother and child It is also presumed that the organisms were introduced into the patient's conjunctival sac A heavy infection in a child of this age might produce a condition not unlike that produced in rabbits by Gourfein (1899)

Thanks are due to Dr C Parsons for permission to publish, Miss P M Weight for secretarial assistance, and Mr A C Allsop for the bacteriological examinations

ADDENDUM

After this paper was written the child had a further flare up of the lesion over the nasolacrimal duct, and, despite the original reluctance to remove this, partial dacryocystectomy was done This lesion showed a characteristic tuberculous infiltration, so we ultimately

Biochemical Evidence

The relevant findings are listed above Significantly high values were obtained for blood fatty acids, serum citric acid, and blood pyruvic acid The urinary excretion of citric and pyruvic acids was excessive Although the former represent only three stages in the long chain of energy changes involved in oxidising glucose, the uniformly high values obtained indicate an accumulation of the products of the C_6 tricarboxylic acid cycle (Breusch 1948) The raised pyruvic acid level may be due to the excessive secretion of insulin (Bueding et al 1942) Derangement of the metabolism of protein and fat due to liver disease may also have contributed to the raised values obtained

Dr H Weil Malherbe informs us that he has found a slight decrease in the serum citrate level in artificial hypoglycæmia This suggests that in the present case the liver did not break down citrate

Histological Evidence

The photomicrograph of a section chosen at random (fig 3) shows that the pancreas contained an abnormal number of islets Many of these islets were abnormally large (fig 4) Although K C Richardson (cited by Graham and Oakley 1950) believes that the variation in size of the normal islets is so great that one cannot diagnose hyperplasia, we are of the opinion that the island here depicted is pathological

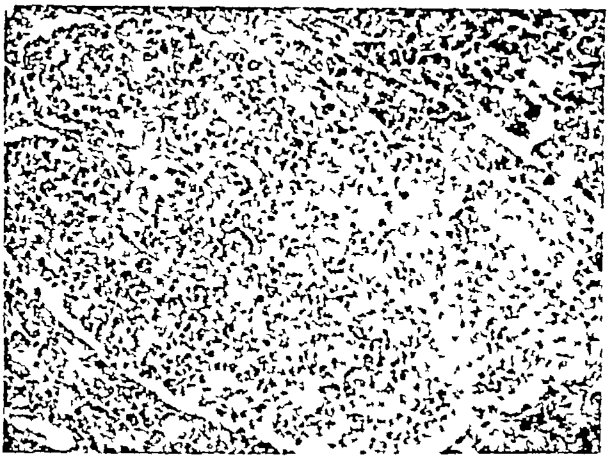

Fig 4—Pancreas showing giant islet measuring 660 µ × 360 µ (1089 cells counted) (Gomori's stain ; × 120)

Effect of Alloxan

The necrotising effect of alloxan on the islet cells, especially the α cells, was observed in all sections In all sections which were examined no undamaged islet was seen Changes took the form of cellular loosening and detachment, with loss of constituent cells in varying degree , some islets consisted of almost empty spaces with a few tattered cells and amorphous granular cytoplasmic debris Many cells appeared swollen, and most presented a matt eosinophilic appearance when stained with hæmatoxylin and eosin, the nuclei appearing small and pyknotic These changes agree with those observed in rabbits by Dunn et al (1943a and b, 1944) In addition, interstitial hæmorrhage was found in some islets (fig 5)

A good account of the cytological effects of alloxan in man is given by Conn and Hinerman (1948), who found similar changes in a portion of normal pancreas removed from a patient who had had 60 g of intravenous alloxan in nine days

Brunschwig et al (1944), however, found only " questionable evidence of injury to a number of cells in some of the islets " Two explanations, of practical importance, have been put forward to account for this discrepancy The first is the fact that alloxan, known to be rapidly eliminated, was administered too slowly, and the second that the preparation of alloxan used may have been ineffective

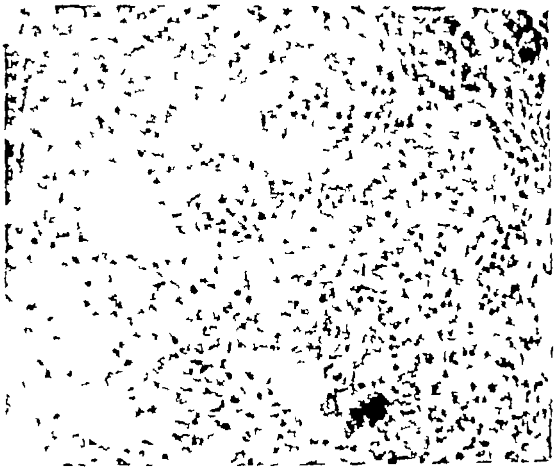

Fig 5—Pancreas showing interstitial hæmorrhage and necrosis of constituent cells in islet of Langerhans (Hæmatoxylin and eosin × 165)

SUMMARY AND CONCLUSIONS

A case of organic hyperinsulinism treated with alloxan is described The toxic effects of alloxan are listed as a warning against its indiscriminate use, and it is suggested that therapeutic results are more likely to be obtained with intravenous injections of 100–200 mg per kg of body weight given rapidly (10–30 minutes) as a 5% solution

Our thanks are due to Dr G Brownlee for much helpful criticism and advice We are also indebted to Dr George Graham, to Dr D Haler, to Mr E A Jones of the Wellcome Research Laboratories, and to Mr D Scott, Mr E A Checksfield, and Mr E Poynter of the Farnborough Hospital. The alloxan was supplied by Messrs L Light and Co , Ltd , Wraysbury, Middlesex

> " The development of the concept of general practice from health centers will require three steps, the first of which is the grouping of family practitioners to practice from health centers This is much more difficult in the democratic than in the totalitarian countries The necessary change of medical mores in democratic countries will require a long and slow educational process, apart from the magnitude of the physical problem of providing the necessary number of centers The second and third steps to extend the practice of clinical medicine to include the diagnosis and prevention of social pathology and to integrate the personal health services into general practice, which are now provided through 'ad hoc' public health agencies for separate population groups, will require in the United Kingdom at least a quarter of a century, for two reasons The general practitioner will have to receive his clerkship training in an environment much different from that which is limited to teaching institutions dealing primarily with cases of illness mostly referred for consultation Satisfactory clerking in turn, will not be possible until students can practice in health centers with physicians as captains of medical teams taking the family as the unit "

TABLE III—ERYTHROCYTE SEDIMENTATION RATES

Case no	Initial period (days)	Actual E S R values (mm in 1 hr)				E S R change (mm)		
		Initial	Start of treatment	After 48 hr	End of treatment	Initial period	First 48 hr	Remainder
1	9	55	30	20	48	−25	−10	+28
2	8	25	34	34	44	+9	0	+10
3	5	42	34	28	30	−8	−6	+2
4	6	80	84	74	78	+4	−10	+4
5	5	50	50	50	56	0	0	+6
6	10	80	66	68	72	−14	+2	+4
7	10	70	44	38	44	−26	−6	+6
8	6	52	46	46	42	−6	0	−4

fallen in the observation period, so the change cannot be ascribed to the treatment In case 4 there was a fall of 10 mm following a slight rise before treatment began, no corresponding improvement was noted in her joints, but she developed well marked euphoria after the first injection (see below)

In the last few days of the course all but one of the patients had a slight or moderate rise in E S R In case 8, where there was a slight fall, the patient's general condition became definitely worse with a great increase in pain, and the fall of 4 mm in E S R certainly did not indicate improvement in the arthritis

HÆMOGLOBIN

Hæmoglobin was estimated three times a week in the initial and treatment periods No significant changes were noted Excluding the patient who had melæna, there was an average gain of 2% in the initial period and a loss of 1% during treatment

EOSINOPHIL COUNTS

If deoxycortone acetate and ascorbic acid exerted a cortisone like effect, one would expect the average eosinophil count to be lower during treatment than in the initial period Table IV shows that this was not so The counts were done three times a week at about the same time of day A dry differential count on 2000 cells was made and the total white cells were counted at the same time This method has been strongly criticised by Rud (1947), and the findings are presented with considerable hesitation

Cases 1, 6, and 7, who had the greatest falls in E S R in the initial period, also had the lowest eosinophil counts In case 8 there was a marked clinical deterioration during treatment and yet the eosinophil count appeared to have fallen, but only two counts were done during treatment, which was limited to five injections so this result is of little significance

TABLE IV—EOSINOPHIL-COUNTS

Case no	Average number of eosinophils per c.mm	
	In initial period	During treatment
1	106 (*3*)	177 (*3*)
2	208 (*1*)	172 (*4*)
3	172 (*3*)	199 (*3*)
4	228 (*3*)	346 (*3*)
5	322 (*4*)	302 (*3*)
6	74 (*5*)	85 (*4*)
7	88 (*6*)	187 (*3*)
8	152 (*3*)	82 (*2*)

Figures in parentheses show number of counts done

MENTAL REACTIONS

In cases 4 and 6 a striking euphoria was noted some minutes after the first injection of deoxycortone acetate and ascorbic acid This lasted for about three hours and was not repeated after subsequent injections In both patients there was some evidence of improvement in the next forty eight hours—case 6 in clinical condition and case 4 in E S R

DISCUSSION

Patients admitted for treatment with deoxycortone acetate and ascorbic acid seemed to progress on a standard plan Before treatment started there was immediate clinical improvement with a fall in E S R This continued for the first two days of treatment, but then nearly every case went downhill This illustrates the great importance of an adequate period of observation in hospital before treatment is begun In the present cases the results would have been much more favourable if the injections had been started on the day of admission

The well established tendency of these patients to improve if admitted to hospital is not easy to explain The most important factor is probably restoration of morale The present patients had read about cortisone in the press and had high hopes that they were to receive an effective substitute The improvement seemed to last 7–14 days and was nearly always followed by deterioration In 5 of our 8 patients the turning-point came in the later days of treatment Whether disappointment at the failure of the initial injections was a factor in the exacerbation must remain an open question

It is certain that deoxycortone acetate and ascorbic acid are no substitute for cortisone The observers who have reported favourably on this combination (Lewin and Wassén 1949, Le Vay and Loxton 1949, Douthwaite 1949, Fox 1949, Robertson 1950, Nashat 1950) agree that the relief is obvious within a few minutes of the injection and is accompanied by exhilaration, it may last hours or days and may be repeated after subsequent injections Some of these patients have been treated as outpatients, and there is no record of any long preliminary observation period in hospital, this point was emphasised by Fox (1949) If the good results are due to the moral effect of cortisone's reputation, reinforced by the euphoria which is sometimes a direct effect of the injections, it would be worth while investigating the value in rheumatoid arthritis of other drugs which produce euphoria, as has been done in pulmonary tuberculosis

SUMMARY

The results of intramuscular deoxycortone acetate and intravenous ascorbic acid in 8 patients with active rheumatoid arthritis are reported

No significant improvement was obtained

Several patients improved between their admission to hospital and the start of treatment, illustrating the importance of an initial period of observation when assessing any new treatment

Euphoria followed the injections in 2 cases and this effect may be partly responsible for the improvement noted by other workers

I wish to thank Dr A H Douthwaite and Dr E R Boland under whose care the patients were admitted for their invaluable help and advice during the preparation of this paper

DEOXYCORTONE ACETATE AND ASCORBIC ACID IN RHEUMATOID ARTHRITIS

K S MacLean
M A, M D Camb, M R C P
ASSISTANT TO DIRECTOR, DEPARTMENT OF MEDICINE, GUY'S HOSPITAL

THE results obtained with deoxycortone acetate and ascorbic acid in a small series of cases of rheumatoid arthritis at Guy's Hospital support the views of Kellgren (1949), Bywaters et al (1950), Copeman et al (1950), and others that, as a substitute for 'Cortisone,' this treatment is completely ineffective Observations were made which emphasise the difficulties of assessing results in rheumatoid arthritis and may partly explain the wide differences of opinion on this treatment

The 8 patients, all women, were observed for at least five days before being given deoxycortone acetate and ascorbic acid During this period they received full passive movements of all affected joints once daily and analgesics in about the amounts they had been taking before admission All of them were seen within two or three days of admission

The course of treatment consisted of 8 daily injections of deoxycortone acetate 5 mg intramuscularly, followed immediately by ascorbic acid 1 g intravenously, except in case 8, where only 5 injections were given because the patient's arthritis was obviously becoming worse and the intramuscular injections were followed by severe pain

Table I gives brief details of the 8 patients on admission

Case 1 had psoriasis, which had been present for two years, this flared up in the latter part of her treatment, new patches appearing on her hands

Case 2 had melæna on the fifth and sixth days of treatment, which was never satisfactorily explained, she had had unexplained hæmoptyses in 1931 and 1944 and hæmatemesis nine months before admission. Her clotting time and prothrombin time were now normal

TABLE I—CONDITION ON ADMISSION

Case no	Age (yr)	General condition	Muscle wasting	Joints affected	Pain on admission	Duration of symptoms (yr)	E.S R. (mm in 1st hr)	Hb (%)
1	57	Bedridden	Sev	Multiple	Mod	7	80	78
2	60	Almost bedridden	Mod	Multiple	Sev	37	25	86
3	47	Immobile through ankylosis of knees otherwise active	Slt	Multiple	Slt	18	42	80
4	63	Bedridden	Sev	Multiple	Sev	24	80	74
5	57	Mobile	Slt	Multiple	Mod	1 1/2	50	70
6	42	Bedridden	Sev	Multiple	Mod	11	80	60
7	46	Mobile	Nil	Hands ankles rt wrist	Slt	3 1/2	70	78
8	16	Mobile	Nil, obese	Hands wrists elbows knees rt sacro iliac	Mod	10/12	50	90

Several patients had had symptoms of arthritis for many years, but they had been deteriorating before admission, and in all cases the rheumatoid arthritis was considered active

CLINICAL CONDITION

The day to day changes in rheumatoid arthritis are not easily assessed In these patients the range of passive movement in the affected joints varied so much from hour to hour that conclusions drawn from such changes would be misleading Assessment was therefore based on clinical findings, particularly what amount of movement the patient could perform This amount no doubt depends largely on how the patient is feeling when examined, but, as Bywaters et al (1950) point out, subjective feelings are a valuable indication of progress in this disease, and it would be impossible to divorce them from the clinical state of the disease Table II summarises the patients' clinical progress in (1) the initial observation period, (2) the first 48 hours of treatment, and (3) the remaining days of treatment

TABLE II—CLINICAL PROGRESS BEFORE AND DURING TREATMENT

Case no	Duration of initial observation (days)	Progress during: Initial period	First 48 hr of treatment	Remaining days of treatment
1	9	Great improvement	No change	Mod deterioration (spread of psoriasis)
2	8	Mod improvement	No change	Mod. deterioration (melæna)
3	5	Mod improvement	No change	No change
4	5	Slight improvement	No change	Mod deterioration
5	5	Slight improvement	Slight improvement	Slight deterioration
6	10	Slight improvement	Mod improvement	Slight deterioration
7	10	Great improvement	No change	No change
8	5	No change	Slight deterioration	Mod deterioration

It is clear that improvement was greatest before treatment began The 2 patients who improved in the first 48 hours of treatment had been improving previously During the remainder of the course no patient improved and 6 deteriorated

Case 1 deteriorated considerably and developed a new manifestation in the cervical spine Clinical deterioration was not obvious until the third day of treatment, but she had slight pain in the neck the day before treatment started, so it is unjustifiable to ascribe the exacerbation to the drugs

BLOOD FINDINGS

The erythrocyte sedimentation rate (E S.R., Westergren), hæmoglobin, and eosinophil count were done every 2 or 3 days In some cases capillary blood was used for E S R because deformity of the joints made venepuncture difficult

These results (table III) accord well with the patients' clinical condition In the initial period cases 1 and 7, who showed great clinical improvement, showed a corresponding fall of over 20 mm in E S.R, cases 3, 6, and 8 had a slighter fall In case 2 a moderate clinical improvement was accompanied by a slight rise in E S R., this patient did badly later, and the initial response may have been largely subjective

In the first forty eight hours' treatment 4 patients showed falls in E S R, but in 3 of them the rate had ntricle The fibrosis extended irregularly through the yocardium, and there was some unevenly distributed thicken g of the endocardium The valves appeared normal An nte mortem thrombus was attached to the wall of the left entricle at the apex. There was no evidence of coronary isease The left kidney showed a well-demarcated area of ecrosis about 4 × 2 × 0 3 c cm. with a surrounding red zone he liver spleen, and lungs showed only congestion. The eritoneum contained some faintly turbid fluid which on ulture yielded only contaminants Nothing else abnormal as found.

Histology.—The sections were all stained with hæmatoxylin nd eosin and Levaditi s stain for spirochætes No organisms ere seen. The myocardium was infiltrated diffusely with brous tissue, some of which was considered to be weeks old, hile in other places it was still being laid down, and patches f myocardial degeneration were present There was only a ery scanty cellular infiltration by an occasional polymorph r lymphocyte No Aschoff bodies were seen. In the left idney (fig 3) the outer half of the cortex was necrotic, apart rom a small subcapsular area There was a surrounding one of hyperæmia A few polymorphs, lymphocytes and ibroblasts were present and some collagen had been laid down. The necrotic area was considered to be not more han a week old. Elsewhere the kidneys appeared normal The liver showed some centrilobular congestion. The lungs howed alveoli full of red blood-cells and pigment-laden phagocytes but no bronchial necrosis or evidence of pulmonary nfection was seen. No *Trichina spiralis* embryos were seen n the heart or in the diaphragm.

DISCUSSION

Since Fiedler s (1900) original description of interstitial myocarditis over 44 cases have been published with an acute, subacute, or chronic course Covey (1942) notes that this disorder occurs mainly in young persons aged 20–30 Sudden death is very common, and the condition is more often recognised post mortem than clinically The usual clinical picture is that of rapidly progressive heart-failure in a previously healthy young person

There is often a history of infection of the upper respiratory tract, as in the present case Finland et al. (1945) have suggested that influenza-A virus may be concerned, they publish two cases of influenza with interstitial myocarditis, and influenza-A virus was recovered from the lungs post mortem in these two cases Schmidt (1948) isolated a virus from a chimpanzee dying of interstitial myocarditis The evidence, however, of the occurrence of myocarditis in human influenza epidemics is so far inconclusive The present case came to necropsy during an influenza-A outbreak, but similar lesions were not found post mortem in two patients who died of influenza in the epidemic and in whom the virus was found.

Other ætiological agents mentioned are *Treponema pallidum, Staphylococcus citreus,* bacterial toxins, and *Trichina spiralis* In the present case no organisms were seen in the heart with Gram s stain, and post mortem culture of the peritoneal fluid yielded contaminants only The appearances were not those of eosinophilic myocarditis caused by sulphonamides as described by French and Weller (1942) A deficiency of vitamin B_1 was considered by Toreson (1944) to be a possible cause, but there was no history of dietary deficiency in the present case and the blood pyruvic-acid level was within normal limits

A zone of unilateral cortical necrosis of the kidney was a feature of the present case and has not previously been reported. Despite the presence of ante mortem thrombus in the left ventricle, the appearances of the renal lesion, by reason of its site and extent, were considered to be those of cortical necrosis and not infarction Either vascular spasm or renal anoxia may have been the cause of the cortical necrosis

We are indebted to Dr C Gray Imrie for permission to publish this case and for his helpful advice

LATE INFECTIVITY IN HEPATITIS

Patrick N Meenan
M.D N U I. D C.P
ASSISTANT PATHOLOGIST ST VINCENT S HOSPITAL,
PATHOLOGIST, NATIONAL CHILDREN S HOSPITAL, DUBLIN

In controlling the spread of infective hepatitis it is important to know how long the patients are infectious The period of infectivity is probably short, but it is uncertain at what stage in the illness it occurs Cases have been shown to be infectious eight days before and seven days after the onset of symptoms (McFarlan 1945), but it is generally accepted that fourteen days' isolation from the onset provides a safe margin (Pickles 1939) The case described here, however, suggests that this period is sometimes barely sufficient

There is general agreement on the incubation period Booth (1928) set the limits at 20–40 days, and they were subsequently narrowed down by Pickles (1939) to 26–30 days The latter limits seem rather too narrow, for Naughten et al. (1950) in an outbreak involving 114 people found that the shortest incubation period was 18 and the longest 43 days, and the present case also supports this view

CASE-RECORD

A probationer nurse aged 20 was taken ill with " influenza " on Jan. 14, 1949 and went to bed She improved in the next few days and resumed duty on Jan 21 Next day she was jaundiced Another nurse had an attack of jaundice, diagnosed as infective hepatitis about a month previously but she was much senior to the patient and no history of more than the most casual contact could be elicited Many other nurses had been at considerably greater risk without contracting the infection.

The patient was at no time very ill and from the onset of jaundice she was allowed up daily though she was confined to the ward which contained three other beds her bed being screened off

On Jan. 26 the patient s parents visited her when she was sitting up in bed Both of them sat beside the bed and on the same side the mother being nearer about a yard from the patient They chatted for about three quarters of an hour, when the mother left and the father moved into her chair and remained another fifteen or twenty minutes Both parents kissed the patient on their arrival and departure Neither had anything to eat while in the ward They had travelled about 100 miles by rail for the visit and left for home immediately afterwards

None of the physicians or nurses attending the patient developed jaundice at any time subsequently, and the patient recovered uneventfully

Thirty two days later on Feb 27 the patient s mother, aged 63 complained of influenza ' and on March 7 she developed jaundice The attack was severe requiring hospital treatment but she ultimately recovered completely In hospital she was fully investigated and infective hepatitis was diagnosed The father, aged 70 showed no sign of infection at any stage Neither of the parents gave any history of a previous attack of jaundice One other case of jaundice occurred locally about the end of February, but there was no contact between the two cases and no other case had occurred in the area for more than six months

"ISOLATED" MYOCARDITIS ASSOCIATED WITH UNILATERAL CORTICAL NECROSIS OF THE KIDNEY

I McLean Baird
M B St And , M R C P
MEDICAL REGISTRAR

J C Burne
M A , M B Camb
ASSISTANT PATHOLOGIST

ROYAL HOSPITAL, SHEFFIELD

"Isolated" myocarditis is relatively rare It is characterised by congestive cardiac failure in a previously healthy young person, and often ends in sudden death At necropsy an enlarged heart is found, but usually no other abnormal findings Histologically, there is degeneration of the myocardium, which is often grossly fibrotic throughout Fiedler (1900) first described this condition as "interstitial myocarditis" Covey (1942) collected 44 published cases and reported an additional one The association of unilateral cortical necrosis of the kidney with isolated myocarditis has not been previously recorded

CASE RECORD

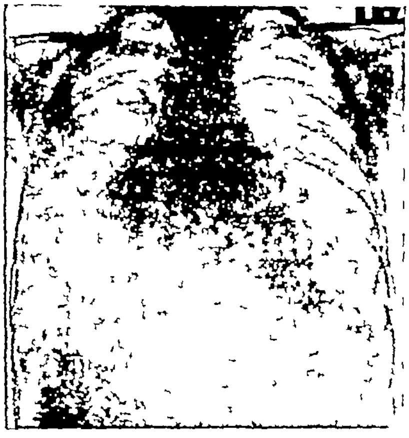

Fig 1—Radiogram of chest on admission showing right half of diaphragm obscured by fluid and heart dilated to right and left

A girl, aged 3 years, had been quite well until January 1949, when she developed a cough and pyrexia Her doctor treated her with a week's course of sulphonamides, and her condition improved On March 8 her symptoms had become worse, and subsequently her condition deteriorated so much that her doctor suspected "whooping cough and pneumonia" and arranged for her admission to an isolation hospital on March 14 On admission there were no physical signs except a few fine crepitations at both lung bases On March 19 the child complained of abdominal pain and developed generalised œdema, ascites, enlargement of the liver, and breathlessness On March 21 partial suppression of urine began, 4–8 oz being passed daily On March 23 she was transferred to Sheffield Royal Hospital for further investigation

On examination she had a temperature of 100 8°F, pulse rate 132, respirations 48 a minute, there was generalised œdema, with slight cyanosis but no venous congestion, the chest moved well, the trachea was central and the percussion note was resonant throughout, there were occasional crepitations at both bases The heart was enlarged to the left, with a rate of 130, the rhythm was regular, and the heart sounds were muffled The liver was enlarged to 3 finger breadths below the costal margin, and shifting dullness was present in the flanks The spleen was not palpable

Radiography of the chest (fig 1) showed that the right half of the diaphragm was obscured by fluid, the heart was dilated to the right and to the left, but there did not seem to be any pericardial effusion, and there was a small effusion on the right side, extending into the horizontal fissure and over the right diaphragm

Electrocardiography (fig 2) showed low potential Q R S complexes in all three leads, with a tendency to right axis deviation The P waves were large and bifid in lead III and inverted in lead I There was also a ventricular extrasystole The electrocardiogram was compatible with severe myocardial damage and was closely similar to other recorded electrocardiograms in Fiedler's disease The common findings are low potential of all complexes with inversion of T waves, slurring and spreading of Q R S complexes, and ventricular extrasystoles of heart block (Finland 1945)

Examination of the blood showed white cells 9800 per c mm. (neutrophils 61%, lymphocytes 35%), erythrocyte sedimentation rate 3 mm in 1 hr (Westergren), Serum proteins 5 5 g per 100 ml (albumin 3 5 g per 100 ml, globulin 2 0 g per 100 ml), serum non protein nitrogen 47 mg per 100 ml and blood pyruvic acid 0 44 mg per 100 ml (within normal limits)

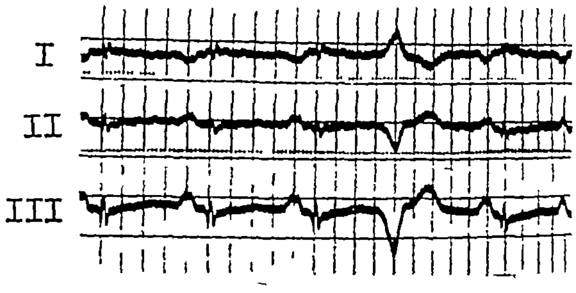

Fig 2—Electrocardiograms showing low-potential Q R S complexes in all three leads, with tendency to right axis deviation ; P waves large and bifid in lead III and inverted in lead I, and ventricular extrasystole

A catheter specimen of urine showed a trace of albumin and no casts, and was sterile on culture

Progress—On April 6 the child developed some dullness and diminished breath sounds at the right base, suggesting a small effusion The 7-day course of sulphadimidine was stopped on April 7 On April 7 radiography showed that the heart remained much enlarged and had probably increased in size The contours were less clearly defined, and pericardial effusion was seen The effusion in the right pleura had increased and was obscuring the right upper lobe The left lung was clear On April 8 the child's temperature had risen to 99 5°F and her pulse rate to 150, with much deterioration in her general condition and cyanosis A paracentesis thoracis on April 8 produced only 15 ml of an opalescent fluid containing a few lymphocytes The deterioration in condition continued, with distressed rapid respirations An oxygen tent did not help, and the child died later that night

Necropsy—The body was that of a well nourished little girl with distended abdomen and œdema of the ankles There was 50 ml of clear fluid in the pericardium The heart weighed 190 g (normal for age 60 g) There was a patchy fibrosis on the epicardial surface, especially over the right

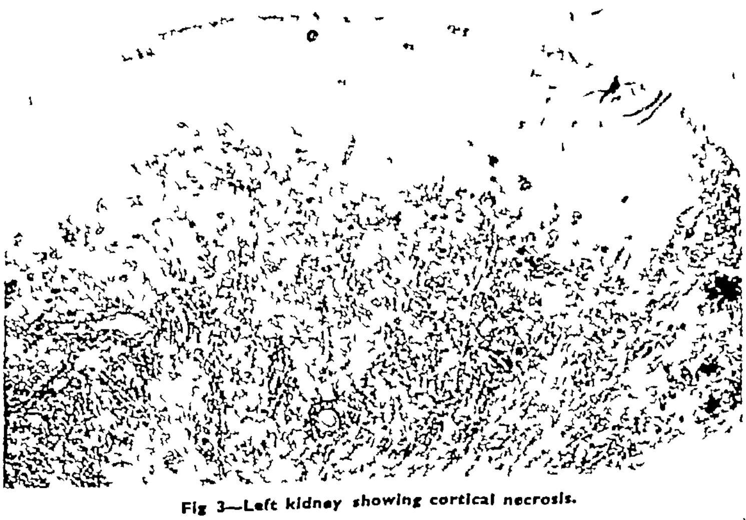

Fig 3—Left kidney showing cortical necrosis.

Medical Societies

ROYAL SOCIETY OF MEDICINE

Treatment of Burns in Large Numbers

THE United Services section met on Feb. 9, with Sir GORDON GORDON-TAYLOR, the president, in the chair, to discuss the treatment of burns in large numbers.

Colonel E. J. PULASKI presented the results of treatment by the exposure method, reintroduced by A. B. Wallace, of Edinburgh. His cases consisted of two groups—one treated within 24 hours after injury, and the other some 4½ days after injury. Like Wallace, he had at first hesitated to expose burns which had taken place more than 24 hours before, but he now felt that this method was applicable to treatment of burns up to a week old. Of 60 cases in the first group, 30 were full-thickness burns and 20 partial-thickness burns. Grafting was carried out, on average, on the 24th day, but now grafting would be carried out earlier.

Describing the procedure on admission, Colonel Pulaski said that debridement and cleansing should be as complete and as gentle as possible. With recent burns this could be done under intravenous morphine, but with older burns light general anæsthesia was used. Cleansing should be carried out under operating-room conditions. He did not give antibiotics locally; but, for large burns, penicillin, 300,000 units daily, was given intramuscularly. After the burned areas were cleansed the patients were put in a warm room and the affected areas exposed, with the extremities elevated. In 24–48 hours a dry crust formed, which gave no pain to touch; and thereafter patients were allowed up as their condition permitted. General therapy now took precedence over local therapy. Patients with burns of less than 15% of body surface were given fluids by mouth; others were given saline and plasma or plasma-substitute on the formula, 1 ml. of fluid per kg. body-weight multiplied by percentage of body-surface burned. In patients with burns of more than 25% of the body surface, automatic feeding by catheter was adopted. Additional fluids were given, where necessary, to maintain a urinary output of 60 ml. per hour.

The advantages of the exposure method were the absence of cross-infection, of "burn odour," and of the so called toxic or septic phase; reduction of physiological complications; small morphine requirements; less acute need for blood and protein intake; improved mental outlook; little weight-loss; and briefer hospitalisation. The problems of this method were that patients complained of discomfort or of feeling cold, and might in fact have chills during the first 24 hours, and some patients might be very distressed at the sight of their wounds (curiosity was a problem when the crust separated, but this could be overcome with proper education).

Colonel Pulaski was not convinced that exposure was the best technique for all types of burns under all conditions; but it did seem satisfactory for burns confined to one side of the body and for burns of the head, neck, and perineum. It had proved suitable in extremes of climate. It was essentially a hospital treatment—good nursing care was still needed.

Surgeon Commander W. V. BEACH, in a paper read for him by Surgeon Commander D. F. WALSH, said that blast injuries and flash burns due to high explosives had long been a serious factor in war at sea; and in field warfare the tendency had been to replace the high explosive bomb by the phosphorus and petroleum types, thereby increasing the proportion of casualties due to thermal effects. After an atomic explosion, outside the lethal 1000-yard radius blast and flash would not be synchronous, since blast settled down quickly to travel with the speed of sound; and so there was every reason to hope that, by educating the public, the majority of flash burns might not be complicated by blast injuries.

It was found at Hiroshima—and this had since been verified experimentally—that the clinical course and prognosis of all burns were adversely affected by even low doses of radiation. The casualties from an atomic air-burst over a large city were now expected to number from 10,000 to 50,000, not 250,000 as formerly forecast; but this estimate did not allow for bombs of a more powerful type than that used at Hiroshima, or for multiple simultaneous explosions. Almost all cases of flash burns would suffer from radiation effects as well, for γ-radiation continued to be emitted for 60–90 seconds after the explosion; the range of neutron radiation was about 700 yards, and survival within that radius could be expected only for those in deep shelters.

While the majority of flash burns would be complicated by radiation, with training of the population to seek shelter even after the explosion, exposure to the full intensity of the irradiation hazard could be greatly reduced. Broadly speaking, among the surviving victims, the more severe the flash burn, the greater was the dose of irradiation received, and thus the poorer the prognosis. The effects of radiation varied, however, and certain phenomena observed after ionising radiation were inconsistent with known physics. In Japan many with marked epilation had recovered. White clothing did not protect against γ-radiation but was a factor in protection against flash. With regard to civilians, much could be done by educating them now to realise the war dangers of bare arms, hands, legs, and faces.

Flash burns would probably be confined to one aspect of the body. Because of the numbers, modification of the optimum treatment would be necessary. For first-degree burns exposure was the treatment of choice; and for mild second-degree burns with vesication this method was equally satisfactory. Blisters should not be excised, but pricked with a sterile needle; or else the fluid might be aspirated via normal skin to prevent infection. Commander Beach thought that under ideal conditions more rapid return to full duty of the patient with deep second-degree burns could be secured by the closed pressure dressing, which also involved less strain on the nursing staff than did the exposure method. In the tropics, however, he treated burns of all depths by exposure. Both there and in fighting ships, battened down for long periods in warm or even temperate waters, it was better than the occlusive dressing, which caused sweating and overheating.

In war an important factor would be the enormous numbers of flash burns that would have to be treated. Burns by flash from atomic explosion would be particularly easy to treat by exposure, since the patients would probably have one sound surface to lie on. Furthermore it might be beyond the capacity of industry and of nursing resources to produce and apply satisfactorily pressure dressings to all for whom they might be indicated under peace-time conditions. Nevertheless, every effort must be made to supply the best, as opposed to the easiest and most convenient, treatment; and he did not think that exposure was best for deep burns, since with this method final healing was delayed. The treatment of shock would probably necessitate the widespread use of plasma substitutes.

Cleaning the burn, except when it was obviously contaminated, was better avoided; when carried out, it must be done very gently. Antibiotic therapy was at present limited to penicillin, streptomycin, and chloramphenicol; in due course 'Terramycin' would doubtless be available. The relative value of topical penicillin was still disputed. In England penicillin was administered both parenterally and topically; in America against established infections reliance was placed on parenteral administration of the appropriate antibiotic. Surgeon Commander Beach was convinced of the value of topical penicillin applied as a powder or in a cream; he used 10,000 units per g. in a base of 'Lanette wax SX,' and trouble with untoward sensitivity was negligible.

With regard to nutrition, Stare, of Boston, administered fat emulsions as a rapid and simple method of supplying adequate calories and at the same time affording efficient utilisation of other elements in the diet.

Although many flash burns would eventually be treated by the open method training should begin now in the proper application of pressure dressings by doctors and first-aid workers.

Mr. WILLIAM GISSANE said that in Birmingham they saw no reason why the easiest and most efficient treatment for a given patient should not be the treatment of choice for that patient. They used the open method for all burns of the face and for most burns of the buttock.

DISCUSSION

It seems clear that the mother was infected by her daughter, who was therefore infectious on the thirteenth day of her illness This is a later stage than has previously been noted The epidemiological implication is that the fourteen days' isolation commonly enforced (where any isolation is enforced) may be too short in some cases It is easy to make too much of one isolated incident in the face of the excellent results obtained with the fourteen day period, more particularly as it is obviously necessary to fix some reasonable time Past experience shows that a fortnight from the onset of symptoms will cover the vast majority of cases, but one is accustomed to think of a patient as infectious early in this period rather than, as in this case, towards the end of it It is not known whether the patient continued to be infectious after the thirteenth day or whether, if isolation had been enforced for another day, the infection might not have been transmitted Fourteen days should apparently be regarded as a minimum rather than a maximum, even though it is almost certainly uncommon for a patient to be infectious thirteen days after the onset of symptoms

The incubation period of the second case—thirty two days—fits in well with an infection derived during the visit to the patient, and may be considered as supporting evidence Why the father was not infected at the same time it is difficult to say, but in view of the parents' ages it is more remarkable that one was infected than that the other escaped The incidence of infective hepatitis drops sharply after the age of 30, and it is unusual in a woman of 63

It is interesting to speculate on whether the infection was contracted by kissing the patient, or by droplet spread during conversation, although, as is usual in these cases, there were no respiratory signs or symptoms The former seems more likely, since it would bring the victim into contact with a higher concentration of virus

SUMMARY

A nurse transmitted infective hepatitis on the thirteenth day of illness to her mother, aged 63

The incubation period in the second case was thirty two days

It is suggested that the usual fourteen days' isolation should be regarded as a minimum rather than a maximum period

FINGER-NAIL KNIFE FOR COMMISSUROTOMY IN MITRAL STENOSIS

THE operation of dividing or splitting the commissures of the damaged valves in mitral stenosis gives considerable relief in selected cases The present tendency at operation is to avoid interference with the leaves of the valves themselves and to enlarge the narrowed opening by dividing along the line of the commissures If the fused tissue is split outwards to the margins of the ring, the two valve leaves are separated and will regain some of their normal function

The fused commissures in these cases are thickened and sclerosed at the stenotic opening but at the periphery they consist of thinner fibrous tissue which splits easily It is usually possible to divide the commissures by digital pressure, the finger being introduced through the auricular appendage, but in some instances where the edge of the opening is unduly firm or even calcified there is a risk of tearing across or into one leaf of the valve The anterior leaf is more liable to damage than the posterior, and rendering it incompetent leads to dangerous regurgitation

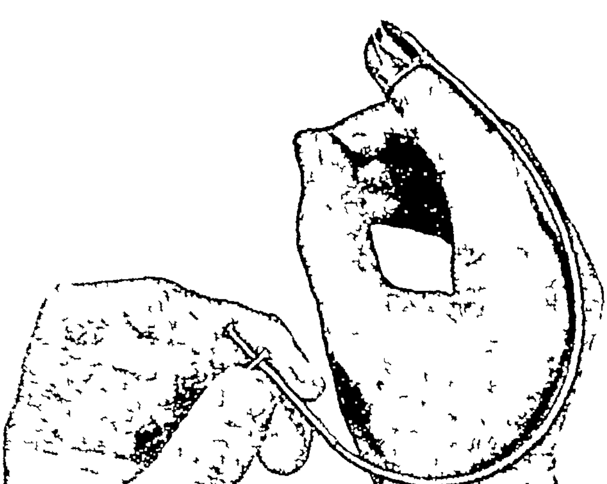

Fig 1—The whole apparatus.

The advantage of a cutting instrument in mitral valvulotomy is obvious if such an instrument can be readily introduced and guided by the finger into the mitral opening Various forms of valvulotome have been described and used, but many of them are difficult to manipulate

The instrument here illustrated is designed to fit on the index finger and resembles a retractable steel finger-nail The appliance has been made by Mr L G Wray, instrument curator at the Middlesex Hospital, on the basis of a cut away thimble The knife, which is about the size of the normal index finger nail lies in a hood attached to the dorsum of the thimble ring It can be advanced or retracted by a cable of the camera shutter type The palmar aspect and sides of the finger are left free for palpation of the mitral opening When the lines of the commissures have been orientated the knife blade is advanced, and a few millimetres of the rolled or nodular margin are nicked The blade is then retracted, and steady pressure with the side of the finger is used to split the membrane out to the edges of the mitral ring

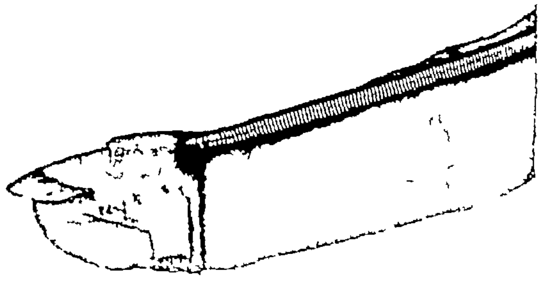

Fig 2—Knife with blade advanced

The apparatus is covered with a smooth finger-cot to eliminate rough surfaces, and when the blade is advanced it punches a small hole through the tip of the cot

The value of this instrument was particularly well illustrated in one case where the valve edges were calcified and visible radiologically With the aid of the finger-nail knife valvulotomy was done in one manœuvre and with a minimum of disturbance

London

Mr **David Matthews** said there was no doubt that with exposure treatment extensive burns healed quickly and the patients were seen to be in good general condition within a few days If necessary, patients could be put in a chair within a week, skilful nursing care was needed but in no great numbers He thought that this method had a large place in the treatment of burns, but doubted whether it was applicable in Britain in winter-time Nor was it applicable if the patient had to make a journey of any distance In these circumstances the absorptive method would be used In the event of large numbers of burns occurring in war-time much of the treatment would have to be undertaken by civilians because there would not be enough medical personnel He thought it advisable that steps should be taken to train the public now without frightening them. He thought that the doctors would have to deal with the fluid-replacement side of the problem and should be trained for this It would probably be impossible under such circumstances for them to be anything but advisory with regard to local treatment He visualised the necessity of mobile medical teams

Sir **Claude Frankau** said the committee on flash burns, of which he was chairman had decided, broadly, that when transporting patients to " cushion " hospitals closed treatment would be necessary They had evolved certain methods for treating burns of the hands and face They had also concluded that if the population was caught unawares casualties would probably be very numerous , the populace of this country never had been " shelter-minded ' There would be a chart on treatment He disagreed with sending medical teams into a city which had been atom-bombed, to treat patients in unaffected hospitals , there was nothing to show that there would not be another atom bomb or other bombing the next day

Mr **D H Patey** thought that the present neglect of antisera was unwise

Surgeon Captain **S G Rainsford** remarked that the exposure method seemed easy, but he scarcely thought it would be practicable in the English, let alone the Scottish, climate The principle of the absorptive dressing was to keep the burn dry He recommended using a hygroscopic paste , a powder of zinc oxide made up in 3% glycerin was admirable for this purpose, for it prevented the part becoming waterlogged and sodden

Reviews of Books

Recent Advances in Physical Medicine

Francis Bach D M , D.PHYS MED , physician Rheumatic Unit St Stephen s Hospital, Chelsea physician in charge Physical Medicine Department, Mount Vernon Hospital London J & A. Churchill 1950 Pp 490 27*s* 6*d*

In collecting his team Dr Bach has cast his net wide no fewer than 38 authorities, both medical and lay, have written articles on a great variety of subjects He has included chapters on physiology, organisation, the school-child, resettlement of the disabled and the training of the doctor and physiotherapist, as well as chapters on physical methods of treatment and the practice of physical medicine in various medical and surgical conditions Dr P Bauwens writes well on electro-diagnosis, with special reference to electromyography , and in a long section on the application of physical medicine to various conditions the editor contributes a detailed article on the rheumatic diseases He discusses especially the ætiology in which the patient's emotional state plays an important part, and briefly but critically analyses what the discovery of the effect of ' Cortisone ' and A C T H. on rheumatoid arthritis may imply An illuminating article by Dr J W T Patterson on physical medicine in the Army shows what real advances were made during the war in training and assessment of physical capability Rehabilitation and resettlement are well described by such authorities as Dr T M Ling and Dr A R Thompson

Atlas of Human Anatomy

Vol II **M W Woerdeman**, M D , professor of anatomy and embryology, University of Amsterdam Amsterdam Wetenschappelijke Uitgeverij N V London Butterworth 1950 642 plates £3 3*s*

Vol. I of this atlas dealt with the bones, joints, and muscles, and vol II, published two years later, is devoted to the viscera (281 figures), the blood-vessels (102 figures), the nervous system (184 figures), and the special senses (75 figures) As in the first volume, the drawings reach a high standard of accuracy and clarity The labelling is generally clear and unequivocal, but both the leaders and their terminal crosses are perhaps slightly too small, and in some cases they are confusingly numerous The B N A terminology is employed, with occasional English equivalents in brackets , the general effect falls strangely on English ears, and might militate against the book in this country in times when the medical student has no leisure to master two terminologies

The section on splanchnology includes 49 plates dealing with the teeth so that the atlas shall be suitable for use in dental schools Several bronchograms have been included to illustrate the subdivisions of the lungs Some of the pictures of the peritoneum are difficult for the student to interpret, and here colour would probably help Some 20 of the book's plates are wholly or partly in colour, but the best use has not always been made of it For example, two colour plates are expended on cross sections of the liver and spleen, while two very complex plates (472 and 473), showing pathways in the central nervous system, are in black and white

A few plates depict the development of the brain but there are no other embryological figures The peripheral nervous system is illustrated by half tone diagrams of individual nerves the cutaneous distribution being shown separately, with autonomous zones shaded In many of these diagrams, however there are several unexplained degrees of shading, which may mystify the student As is customary in anatomy books, the dermatomes are lent a spurious air of reproducibility by being drawn with great precision

The blood vessels are also dealt with on a diagrammatic plan with " ghost " backgrounds of bones and occasional muscles This scheme renders the book a systematic rather than a regional atlas, and to this extent reduces its value to the student Professor Woerdeman refers to " a special volume dedicated to regional anatomy ' but it seems that this is not to appear in this country If so, this is a great pity, since the main function of an atlas is surely to act as a two-dimensional dissection when a three-dimensional one is not available One would learn almost nothing of the relationships of nerves and arteries from the two existing volumes It is to be hoped that a third will after all be forthcoming

Surgeons Twoe and a Barber

Being some Account of the Life and Work of the Indian Medical Service (1600–1947) **Donald McDonald** London Heinemann Medical Books 1950 Pp 295 42*s*

" The history of the Indian Medical Service was written once for all by Dixon Grey Crawford and published by him in 1914 " Thus opens the preface of the present work, which brings the story up to the dissolution of the service in 1947 For completeness' sake Lieut.-Colonel McDonald follows Crawford in dealing first with the prominent men and events in India from 1600, after first recording the discovery of India in 1498 by Vasco da Gama The founding of the East India Company in 1600 was followed by the dispatch to India of four ships each of which carried " Surgeons twoe and a barber " hence the title of this work In the account of the next century and a half McDonald closely follows Crawford in dealing with the most prominent men and events, but in a more popular form and in chronological order , some additional information based on studies of early records is included It was not until 1764–79 that the presidency medical services of Madras and Bengal were constituted from the medical men then serving in India , in 1896 they were combined into one general service for the whole of India The mutiny in 1857 resulted in the Crown taking over the government of India , numerous administrative changes resulted in the

When an atom bomb dropped, all the burn casualties would happen in a few moments. For these the most practicable and easiest method was desirable. Injuries might be complicated by radiation effects and the effects of blast; so preparation must be made for burns associated with other injuries. With open wounds including burns the aim should be to delay infection until definitive measures could be planned. With all these injuries there was much to be said for the early cover of open wounds by a closed dressing. He believed that at casualty-receiving hospitals the simplest mass-method was to cover burns by dressings and to give antibiotics locally and systemically at the earliest possible moment.

In Birmingham they advocated closed dressings for all serious burns of the body and limbs. By this method the depth of burns could be accurately assessed about the 14th day, when skin grafts for full thickness burns could be started. The optimum time was the 14th–17th day; and where a burn was really extensive, needing perhaps repeated use of the same donor site, surgical skill was especially important. Split skin grafting was an art acquired only after long practice.

Treatment of shock, Mr. Gissane continued, was the first priority. A burn with partial skin loss might result in considerable plasma loss; and partial skin-loss areas should be included in estimating the total area of the burn. Shock from plasma loss could be expected in burns of 15% or more of the body-area in an adult, and of 10% or more in a child, and the aim should be to replenish the plasma before clinical shock manifested itself. Generally speaking, the smaller the area of the burn, the longer the plasma loss took to reach a dangerous level.

Mr. A. B. WALLACE said that no one method was suitable for all burns, but there must be a simple procedure for mass treatment. The two problems in mass burn casualties were (1) to save life where possible, and (2) to limit infection. In general, civilians with minor burns would have to be treated as outpatients; but from the point of view of the medical officer in the Services, concerned to restore the man to fighting fitness, a minor burn was just as important as a major burn. A simple classification of superficial or deep burn was all that was necessary.

The method of local treatment adopted must give a dry surface in the shortest possible period, and the surface must be kept dry.

The "rule of nine" (modified Berkow's table) could be adopted in regard to transfusions, fluid requirements, and urinary output. In the treatment of shock, burns of 9% surface-area in children and 18% of surface area in adults could be controlled by oral therapy. Burns beyond these extents required intravenous fluids. An adult should be given plasma and saline at the rate of one bottle of each for each 9% of total body area that was burned; children should receive half this amount. The urinary output per hour ought to be 54 ml. for adults and 27 ml. for children, and the daily fluid intake, again on the "rule of nine," should be 9 times 9 ml. per kg. body-weight in children, and 9 times 6 ml. per kg. in adults. For a superficial burn the proportional intravenous fluid requirement was two bottles of plasma to two of saline; and for a deep burn one of plasma to two of blood and one of saline.

Mr. Wallace preferred the term "absorptive dressing" to "pressure-dressing"; on no account should pressure be applied to the tissues. This method was interchangeable with exposure. He did not agree that with deep burns exposure delayed healing. Burned areas should be grafted as soon as possible. Exposure gave immediate control of infection, even with penicillin resistant organisms.

Major H. L. WOLFE said that in the event of an atomic explosion burns would be due to people being trapped in burning buildings, &c., or to flash burns. At Hiroshima 70,000 people were killed and 70,000 injured; about 20–30% of deaths were due to flash burns (some might have died later of X-radiation). It was estimated that if people were caught in the open, as in Japan, 65% would have burns, perhaps associated with other injuries; and of all burns 85% would be due to flash burns and 15% to fires.

Leader-Williams and Smith[1] had estimated that in an urban area with a density of 43 persons per acre, as in London, the total number of casualties would be about 27,000; about 2500 of these would be due to burns. Flash burns would occur on exposed parts, and elsewhere if the clothing caught fire, which dark clothing was especially liable to do. In a clear atmosphere flash could cause burns up to 2½ miles away. Among the civilian population, who would be mostly in houses or shelters, there would be a smaller number of flash burns, but the number of burns due to fires in buildings would be greater. In a well organised city with adequate warning and proper shelters, the number of casualties should approach nil. Obviously one could not get this result, and the average figure for burns would be 2000. In the Services the numbers would depend on the conditions in which the personnel found themselves.

Group Captain G. H. MORLEY discussed methods of limiting casualties, especially from irradiation. Light coloured clothing and any kind of covering to the skin gave some protection; and he advised slacks for women and light-coloured uniforms for civil defence workers. People on essential services should be issued with gauntlets, preferably of 'Nylon,' on the lines of a Bunyan bag. In considering the warfare of the future, saturation bombing should not be forgotten; and many people might be unable to get immediate medical treatment. There ought to be some "self help"; and Group Captain Morley suggested that every person should carry a 1 oz. pack of an approved application for burns, with appropriate instructions on it. Simple treatment methods would be required. There would be a place for skin banks, and surgeons skilled at skin grafting eyelids would be needed to prevent blindness in certain cases of burns of the face. The right approach to the problem of treating mass burn casualties was best summed up in the Scout motto: "Be prepared."

Surgeon Commander J. J. KEEVIL said that his experience in the late war convinced him that sorting teams would be essential. In this respect some discipline would have to be recognised, and there would have to be a wider application of the ideas of first aid which Sir James Cantlie had in 1910. Efforts must be directed towards finding methods of treatment which made transport easy and which could be applied by the relatively unskilled.

Surgeon Lieut.-Commander (D) JOHN BUNYAN, R.N.V.R., pointed out the advantages of the envelope method of treatment, which provided for mobility and prevented secondary infection. Moreover, when there were mass casualties, it enabled patients to be looked after by friends and relatives. He urged the importance of positive first-aid, to relieve pain and reduce the secondary effects of the burns. When thousands of casualties had to be attended to, asepsis might have to give way to antisepsis. He illustrated his remarks with a colour film showing the good results obtained with the envelope technique.

Mr. PATRICK CLARKSON confirmed the value and practicability of the exposure method. He found this slower than others—even in superficial burns the crusts took 3 weeks to separate completely—but this would be offset in the case of mass casualties by other advantages. It was always a hospital procedure; it was not suitable for circumferential trunk burns, but might become so if adrenocorticotropic hormone (A.C.T.H.) was found, in fact, to allow patients with even extensive burns to be ambulatory throughout. He favoured replacing fluid, electrolytes, and colloid empirically rather than by a formula. Altemeier's collagenases for slough removal were promising. The outstanding training need at the moment was diffusion of the established healing techniques of plastic surgery among general surgical trainees. He had been told by those who had treated β particle burns that in future they would not treat these conservatively but would remove the affected band skin early and replace it by planned pedicle abdominal flaps.

Annotations

THE COXSACKIE VIRUSES

HE name of Coxsackie, the small town near New York re the prototype was isolated, is now applied to a sized and still expanding group of viruses which ickling mice produce myositis, loss of muscle power, death Members of the group are widely distri d in the United States, and they have been isolated i patients suffering from paralytic and non-paralytic omyelitis, aseptic meningitis, "summer grippe," and rodynia or epidemic myalgia, as well as from healthy ple In size (10–12 mμ), physical properties, and aviour they resemble the laboratory strains of polio elitis virus According to their pathogenic properties suckling mice Dalldorf divided them into A and B ins, A causing myositis only, whereas B also produce ere neurological lesions including cystic degeneration large areas of the brain There is no type specific erentiation within group B, but at least 7 immuno ically distinct types have already been differentiated group A. Extending the work of Sickles and Dalldorf,[1] lnik and Ledinko[2] at Yale have recently confirmed reliability of the neutralisation test for following the munological reactions in infections with the Coxsackie uses They have also shown that different types of us can be distinguished by complement fixation, and at the time of appearance of complement fixing anti dies in patients is quite distinct in infections with two pes of the virus Coxsackie viruses have usually been olated during outbreaks of infectious disease or from tients known to have certain diseases, and in many ses there has been an associated rise in neutralising id complement fixing antibodies Infections in labora ry workers who have developed an acute febrile illness ith thoracic or abdominal pain after working with the rus have also been followed by a similar serological sponse Experienced workers with these viruses are owever still troubled by the thought that association ith a disease does not necessarily imply a causal relationip, and, as Dalldorf remarked, we are still in the nomalous position of having discovered the cause of a isease before discovering the disease

In 1949 Finn and colleagues[3] described an outbreak of pidemic pleurodynia, one of the clinical conditions hought to be caused by a Coxsackie group-A virus, in Boston, and they have recently[4] isolated from stored hroat washings of these patients a virus antigenically imilar to the "Connecticut 5" virus isolated by Melnick rom a case of non paralytic poliomyelitis Stored sera ollected from these patients during the first 4 days of illness contained no demonstrable antibodies, whereas amples collected 10 days later completely neutralised the virus It was also shown that this strain bore no antigenic relationship to certain other members of the Coxsackie group, and this raises the important point that different immunological types may be responsible for different clinical conditions In another recent investigation Huebner and his colleagues[5] studied a small outbreak of acute febrile illness and isolated Coxsackie virus group A type 2, from the fæces of all those affected No clinical diagnosis could be made from the patients' symptoms, which included headache, muscle pains and stiffness, nausea and vomiting Epidemiological associations of virus isolation with illness under such conditions are unjustifiable, so Huebner and his colleagues extended their observations to the rest of the small community in which their patients lived Five other strains of the type 2 virus were found in normal people scattered in various parts of the area, and 77% of 158 inhabitants possessed neutralising antibodies Three additional types of Coxsackie virus were also isolated during the survey, and not a single case of poliomyelitis or meningitis was diagnosed in the area throughout the summer and autumn when the investigations were in progress These isolations of virus from healthy people show that the organism may be widely prevalent in a community and that the danger of spurious associations with different types of illness is very real On the other hand, a similar situation exists with poliomyelitis virus, and excessive caution may be as dangerous as jumping to rash conclusions Laboratory evidence shows conclusively that the Coxsackie viruses do invade the human body, and it seems unlikely that such invasion cannot on occasion be recognised clinically Huebner and his colleagues are trying to solve the Coxsackie puzzle by intense epidemiological investigations in a small community, Melnik and the Yale University workers are tackling it from the laboratory angle They have already extended our knowledge, but the challenge remains—find the diseases

EPIDEMIOLOGY AND THE WORLD HEALTH ORGANISATION

In his address to the epidemiological section of the Royal Society of Medicine on Feb 16, Dr Yves Biraud, the French director of the Epidemiological Services Division of W H O, was able to give an encouraging account of international efforts now being made against communicable diseases After tracing the origins of W H O's work in quarantine and epidemic intelligence, and paying tribute to the earlier activities of the Office International d'Hygiène Publique, the Pan American Sanitary Bureau, the Health Organisation of the League of Nations, and UNRRA, he described the world-wide intelligence system developed by W H O since it took over in December, 1946 Based on the epidemic-intelligence stations at Geneva, Singapore, Alexandria, and Washington, this is now primarily a wireless system, with confirmation by telegraphic and other communications Geneva alone received 6500 separate reports last year, and the world is substantially covered, with the exception that the U S S R has not collaborated since 1937 On the quarantine side, the unsatisfactory state of adhesions to the various conventions makes the promulgation of the new international regulations, to be considered by a special meeting at Geneva in April before the World Health Assembly, an urgent as well as an important matter. Dr Biraud emphasised the advantages of the new procedure by which if a country is unwilling to adopt a regulation, it must positively contract out of it—instead of negatively refraining from ratification

The coördination of research on communicable diseases is, he said, effected mainly by expert committees, and the new system of large panels of experts, from which members are chosen according to the agenda of the particular meeting, allows for adequate geographical representation and for flexibility The influence of these committees lies primarily in making technical advances widely known and diminishing the delays in their application Though direct research is not undertaken by W H O., grants are made to stimulate and coördinate investigations on subjects in which W H O is interested, examples being the World Influenza Centre at Mill Hill and the Brucellosis Centre at Copenhagen, and the Tuberculosis Research Unit at Copenhagen which is investigating both B C G vaccines and the statistical results of the many millions of B C G inoculations Field research is also undertaken or stimulated thus studies are being made of fæcal vibrios in Madras, of the delimitation of endemic yellow-fever areas by the mouse protection test, and of vaccination of dogs against rabies

zenith of the service being attained by the end of the 19th century All this is told in detail in the present volume

Of greater interest is the history of the decline of the service during the first half of the 20th century, for the outstanding events took place after the publication of Crawford's work The first crucial blow was *struck at the service by Lord Morley's order of 1007 that* "no further increase of the civil side of the service can be allowed" The lengthy previous recruitment of highly *qualified men through keen competition* at once slumped to such an alarming extent that the order was not enforced, but recruitment never recovered The Montagu-Chelmsford report of 1018 and the later Indian Round Table Conference led to loss of all confidence in the future of the service and the final cessation of competitive examinations for officers The story of the long series of committees on the medical services in India, with no resulting action, is fully recorded The simple fact is that the good work of the Indian Medical Service professors of the medical colleges of India in educating many thousands of able Indian doctors during a century or more inevitably led to service appointments on the civil side being handed over steadily to increasing numbers of well-qualified Indian practitioners The second world war, with very numerous Indian volunteers, led *to a manyfold increase* of Indian *army* medical officers, to the formation of the present Indian Army Medical Corps, and to the dissolution of the Indian Medical Service in 1947 when political events (which are excluded *as* far as possible from this work) resulted in the government being handed over to Indians

Colonel McDonald's comprehensive work brings out the versatility of I M S officers over a long period in administrative, scientific, clinical, and research branches Many besides the surviving members of the service and their friends will be interested in reading this illuminating record of a medical service which has probably never been surpassed

Pathology in General Surgery

Paul W Schafer, M D Chicago University of Chicago Press, London Cambridge University Press 1950 Pp 581 £6 11*s* 6*d*

In this book the author keeps well to the fore the clinical aspects of general surgical *diseases and correlates* them with the macroscopic and histological appearances The *greatest value of the* work *lies in its* 495 *illustrations*, almost all in colour A surgeon familiar with the appearances shown is in the best of positions to devise rational methods of treatment, and for this *reason* by *itself* the book would be a useful possession In addition Dr Schafer discusses succinctly but clearly the views that are held as to the inner meaning of the pictures *revealed* by the microscope, and at the end of each section he supplies a useful list of references He does not confine himself absolutely to pathology but reviews current practice in therapeutics The book will certainly appeal to those engaged in the teaching of clinical surgery

Researches in Binocular Vision

Kenneth N Ogle, PH D, research consultant in the *Section of Ophthalmology, Mayo Foundation* and Mayo Clinic, Rochester, Minnesota Philadelphia and London W B Saunders 1950 Pp 345 37*s* 6*d*

Most of this book is devoted to the problems of dissimilar images on the two retinæ, but the text also contains a full discussion of the fusional processes in normal binocular vision As an exposition of the physiology of normal and abnormal binocular vision the book is unique, both in its scope and its thoroughness Its inspiration has come from the work of Ames and his associates at the Dartmouth Eye Institute, and the theoretical and clinical aspects of aniseikonia therefore loom large The substantial contributions made by Dr Ogle himself to the problems of binocular vision take their due place in this well balanced exposition of a difficult subject The account of studies on the longitudinal empirical horopter is particularly good

This book is a record of intensive and inspiring work but also an obituary notice That after 18 years the Dartmouth Eye Institute was closed down because of personal difficulties is a sad reflection on human wisdom

Textbook of Bacteriology (2nd ed London H Kimpton 1950 Pp 491 40*s*) —*J M Dougherty* and A J Lamberti have thoroughly revised their book. It is written for the science student or for those taking bacteriology in the premedical *course*, *and for such students*, and possibly also for senior nurses, it gives a clear and reliable account of the subject

A History of Biology (2nd ed London H. K Lewis 1950 Pp 579 35*s*) —That the teaching of science should be given a historical approach has long been thought desirable, but the difficulty of avoiding a mere miscellany of biographical titbits has deterred many teachers from making the attempt. Prof Charles Singer's *History of Biology*, first published in 1931, has shown how the subject can be presented satisfactorily After a review of ancient science, its later decline, and its revival in the 14–16th centuries, he discusses the nature and origin of modern scientific method and thought and then provides what is virtually a series of histories of the great problems in biology The result is both readable and intellectually satisfying to the student of biology, and well deserves its subtitle of '*A general introduction to the study of living* things" It could also be read with profit by the non scientist wishing to learn something of the basic problems with which biologists are faced

Food Poisoning (3rd ed London Leonard Hill 1950 Pp 318 17*s* 6*d*) —Mr Elliot *B Dewberry*'s compilation (the word is his own) describes the causes, signs, symptoms, and methods of prevention of the more or less acute diseases attributable either to articles of diet harmful per se or to food containing pathogenic bacteria or bacterial toxins. The plan of the book is queer part I is devoted to the history of food poisoning and to salmonella infections, part II to staphylococcal food poisoning, to poisoning by metals, fungi, plants, and shellfish and to food allergies, and part III to botulism and the laboratory investigation of food poisoning Parts I and III and the chapter on staphylococcal intoxication are excellent, but the chapters on the more esoteric forms of poisoning might be enlarged with advantage If an account of poisonous plants be included it is not of great value unless the reader is enabled to identify the plant responsible, and some mention might be made of the dangers of fruit and vegetables sprayed with one of the persistent organic phosphates With these reservations the book can be recommended *If we have a doubt it is on* the audience addressed for the sanitary inspector, the physician, the bacteriologist, and the food manufacturer all see food poisoning from different aspects But each will learn something from this book, and for further information on detail an imposing list *of references and an adequate* bibliography are provided. An admirable luxury in such a book is the gallery of portraits of those who have contributed to the subject To be useful *the plates of fungi should* be in colour, and those of bacteria, motor vans, and other people's laboratories tell us nothing at all

Symposia on Quantitative Biology Vol XIV *Amino Acids and Proteins* (Cold Spring Harbor, L.I, New York Long Island Biological Association 1950 Pp 217 $7) —The first of these symposia was held at Cold Spring Harbor in 1933 and there has been one each year since that time except for a break of three years from 1943 to 1945 The subject selected has varied from year to year Protein chemistry was the topic in 1938 but the advances made in the eleven years justified devoting *another symposium* to this subject in 1949 Nucleic acids and nucleoproteins were discussed in 1947 As was natural, the participants at the symposium were mostly American, *but papers* were contributed by Fromageot (France), Pedersen (Sweden) Linderstrom Lang (Denmark), and several by British scientists (Synge, Danielli, and Sanger) The 22 papers *included in this* volume deal with many aspects of protein chemistry Most of them were highly specialised, but Murray Luck's article on the liver proteins is more general, *and the paper* by Kaufmann and others on the localisation of cellular proteins by enzymatic hydrolysis is accompanied by beautiful and instructive photographs Dorothy Hodgkin's paper on X ray analysis and protein structure is also freely illustrated by diagrams and photographs Much of the work reported at this *symposium* has been published in the specialised journals, but volumes of this high standard have a real place in international scientific literature

A C T H and Cortisone in Hæmatology

It is now well known that 'Cortisone' and the pituitary adrenocorticotropic hormone (A C T H) produce profound metabolic changes in normal people and have considerable, if temporary, effects in the 'collagen" diseases These substances are also being widely tested in certain hæmatological disorders After the observation, originally reported by DOUGHERTY and WHITE, that the adrenal cortex hormones reduced lymphoid tissue and caused dissolution of lymphocytes, it was natural to see whether A C T.H and cortisone would reduce the hyperplastic tissue in such conditions as lymphatic leukæmia and lymphosarcoma The early results were encouraging, and so physicians have gone on to test these substances in other forms of leukæmia and in Hodgkin s disease

DAMESHEK and his co-workers [1] found that neither of 2 cases of myelocytic anæmia responded to A C T H. , but of 6 cases of acute or subacute lymphatic leukæmia all except 1 (which was in an adult) had remissions The 5 cases which responded were all in children , in 4 the bone-marrow and peripheral-blood picture became normal or almost normal during the remissions, and there was an increase of hæmoglobin, reticulocytes, and platelets, suggesting that the A C T.H actually stimulated the remaining normal marrow , swollen lymph glands, spleen, and liver also returned to normal size This result was obtained with a dose corresponding to about 80 mg of Armour standard daily for fourteen days, after which the dose was gradually reduced to 40 mg twice weekly The remissions were being maintained at the time of the report , but when in 1 case the A C T.H was stopped the leukæmia relapsed. Further experience has shown that in acute leukæmias relapse takes place sooner or later, and an unfortunate feature of these relapses is that the patients no longer respond to A C T.H or cortisone STICKNEY et al [2] used larger doses , they gave 200 mg of A C T.H , or 200–300 mg of cortisone, daily for twenty to thirty days in adults, and 50–75% less for children Of 12 patients with acute leukæmia who received cortisone, 2 had complete remissions—i e , the patient was clinically well, and blood and bone marrow were no longer leukæmic Of these 2 patients 1, aged eighteen, relapsed five weeks after treatment was stopped and did not respond to further A C T H or cortisone , and the other, aged ten, was still well after three weeks A C T H was given to 6 patients with acute leukæmia , 1 had a complete remission after receiving a total dose of 1 g , and the remission had been maintained for sixteen weeks SPIES et al ,[3] however, reported different experiences Of 5 cases of acute leukæmia treated with A.C T H 3 responded satisfactorily One patient remitted after fourteen days' treatment with 100 mg A C T H daily and the remission was maintained for five months , then a second similar course of A C T.H again produced a remission, which lasted six months Another patient, a boy of seven with acute lymphatic leukæmia, responded quickly to A C T H , but within twenty-four hours of stopping treatment there was clinical and hæmatological evidence of impending relapse, so treatment was resumed and was maintained for forty-three days, when he had had 1750 mg after twenty-nine days he again relapsed, but responded once more after nine days' treatment Results like those of SPIES seem to be exceptional , most reports indicate failure to respond to second courses of A C T H. or cortisone FARBER and his colleagues [4] believe that in acute leukæmia the results with A C T H and cortisone are inferior to those obtained with folic-acid antagonists (aminopterin and amethopterin), the remissions being shorter and failure with second courses more common Of 17 children treated with A C T H , 5 had complete remissions which lasted up to ten weeks , cortisone 100 mg daily was given to 3 affected children, with remissions in 1 They noted that A C T H or cortisone would produce a remission in patients who had become resistant to folic acid antagonists, and vice versa , and they suggested that results might be better if the two forms of treatment were combined

Since A C T.H. acts specifically on lymphoid tissue it might be expected that the chances of remission would be greater in lymphatic than in myeloid or monocytic leukæmia but so far the evidence is conflicting Some reports do not state the type of leukæmia, and when primitive cell forms predominate in the blood and bone marrow it is often very difficult to decide whether an acute leukæmia is lymphoblastic or myeloblastic All seem agreed however, that monocytic leukæmia does not respond at all PEARSON and ELIEL [5] have stated that in children and adults with acute granulocytic or acute lymphatic leukæmia "temporary remissions can be induced with considerable regularity," but monocytic leukæmia was unaffected They gave A C T H or cortisone to 10 adults and 80 children with acute leukæmia, and good remissions followed in 4 adults and 9 children Unfortunately they confirm earlier reports that remissions are short—3–8 weeks in their cases—and refractoriness soon develops They also confirm the observation by FARBER that patients who have become refractory to folic acid antagonists will respond to A C T H or cortisone A C T H and cortisone might also be expected to affect chronic lymphatic leukæmia, but the results have been curious , the enlarged lymph glands, spleen, and liver shrink rapidly, but the blood and bone marrow pictures remain unchanged [2 5] Results in lymphosarcoma have been conflicting , SPIES et al [3] reported a good response to cortisone in 2 patients , PEARSON and ELIEL [5] found moderate benefit in 2 cases, 1 of which after relapse, responded to a second course These drugs have no effect in Hodgkin s disease or chronic myeloid leukæmia [5] PEARSON and ELIEL treated 2 patients with myeloma , in

Assistance to countries in campaigns against particular diseases sometimes involves aid in emergencies, as in the cholera epidemic in Egypt in 1947 and the more recent typhus epidemic in Afghanistan, but chiefly consists in providing specialised technical staff to help a large number of countries in starting or intensifying campaigns against an even larger number of communicable diseases the foreign experts in the teams are "matched" with local experts, with obvious advantages W H O has also assumed technical leadership in the health aspects of other bodies' programmes, some of them very large, such as the $4 million allocated to health work in the United Nations Programme for Technical Assistance

The impression left on Dr Biraud's hearers, enhanced by his unique experience of 25 years as an international medical civil servant in this field, was that W H O is not only worthily carrying on the work of the older organisations but is making a new and remarkable contribution to the reduction of communicable disease throughout the world

PREVENTION OF HÆMORRHAGIC DISEASE OF THE NEWBORN

WHEN it was found that the level of prothrombin in the blood of infants is normally low from about twelve hours after birth till the end of the fifth day, this period was recognised as that in which hæmorrhagic disease of the newborn occurred The discovery of vitamin K and of its action in raising the level of prothrombin in the blood suggested a means of treating this condition, and possibly of preventing it Treatment of infants with hæmorrhagic disease with vitamin K or its analogues has, however, never been really satisfactory, and all authorities recommend blood transfusion as well A possible way of preventing the disease was to give vitamin K to an infant immediately after delivery, or giving vitamin K to the mother some days before the labour would raise the infant's prothrombin concentration above danger point Before hæmorrhage is likely, the prothrombin concentration in the blood must be grossly reduced—to about 15% or below

It is now twelve years since these facts became known, but obstetricians and pædiatricians are still doubtful of the value of the prophylactic administration of vitamin K, because the reported results have been conflicting In 1944[1] we concluded that, despite differing reports, a case had been made out for the prophylactic use of vitamin K and its analogues, especially since the vitamin is non toxic in the doses recommended, and it seemed to be an advantage to have the infant's prothrombin concentration above danger levels throughout the first five days of life Since then other reports have indicated that hæmorrhages take place in infants even though the prothrombin concentration is normal For instance, Falls and Jurow,[2] who observed the incidence of retinal hæmorrhages in infants whose mothers had received prophylactic vitamin K, confirmed once again that this treatment does raise the infant's prothrombin level, the figures being higher than those for infants of untreated mothers Nevertheless, of 33 infants 8 had retinal hæmorrhages, and they therefore concluded that there must be other causes of hæmorrhage This lack of complete correlation between hæmorrhagic incidents in the first five days of life and the prothrombin level in the blood is now sufficiently well known to have reached the textbooks, but the other causes of hæmorrhage have not been clearly defined

In this issue Dr Hay and his colleagues in Liverpool record the results of a large scale effort to answer this question of the prophylactic value of vitamin K The report deals with no less than 4602 infants whose mothers had received prophylactic vitamin K, and a control group of 12,136 infants whose mothers had had treatment In the first group 11 infants had hæmorrha- disease of the newborn, while in the second the affect infants numbered 23, the incidences were therefore in 418 in the prophylactically treated group, and 527 in the control group From these figures they concl that prophylactic vitamin K has no effect on the incide of hæmorrhagic disease In the absence of blood studi however, we do not know whether the prothrom concentration in the 34 affected infants was below dang level, and therefore whether prophylactic vitamin had raised the prothrombin of the 11 infants of the fi group, or whether vitamin K could have been expec to have had any effect on the actual hæmorrhages in the cases The Liverpool workers admit the difficulty of excluding other causes of hæmorrhage, and the na of their investigation obliged them to depend on th opinion of the pædiatrician who saw the patient at the time of the bleeding that hæmorrhagic disease wa "the most likely diagnosis" The result is that though the negative evidence is impressive it is not yet conclusi and so long as it seems possible that vitamin may prevent some cases of hæmorrhagic disease shall stick to our former opinion that it should given

PSYCHOLOGICAL PROBLEMS OF MOTHERS AND CHILDREN

FOR each of its round table conferences the Josi Macy Jr Foundation, New York, brings together a team of authorities on some matter of topical interest The Third Conference on Problems of Infancy and Childhood[1] dealt with three topics (1) the anxieties of mothers as expressed to physicians, (2) the psycho logical situation of mother and child on return from the hospital, and (3) the emotional reactions of children to tonsillectomy and adenoidectomy

It was agreed that mothers who are given anticipatory guidance and opportunities for discussion at the maternity hospital, before returning home, experience much less anxiety about their infants than do mothers who are not prepared in this way Among mothers who received no such guidance the chief anxieties were found by several observers to concern crying, hunger, feeding problems, vomiting, failure to gain weight, constipation, noisy breathing, and a rash on the face Complaints by mothers regarding illness in their infants were of three types (1) connected with a real disorder, (2) determined by contemporary outlook on matters affecting babies, and (3) prompted by maternal psychopathology The conference agreed that the mother should know in advance the doctor who is to look after her baby, and the relative discontinuity of medical care in urban communities was deprecated

Dr Sibylle Escalona emphasised that the period immediately after returning home is crucial for the subsequent development of the mother-child relationship In this period the mother and the whole family are especially open to suggestion, and so this is a good time for trying to influence the new family situation created by the arrival of another member The hospital practice of denying mother and baby the chance of becoming intimately acquainted, from the day of birth, is inimical to secure mother child relationship The present trend however, is towards "rooming in", and this als enables the mother to return home with greater knowledge of baby management, and thus with great confidence

Dr Lucie Jessner and Dr Samuel Kaplan described the observations on the emotional response of an unselecte group of children to tonsillectomy In children und on the other hand, has always insisted on professional privilege which is independent of the wishes of the patient French doctors do not accept the view that the latter's consent removes the main objection to publication in court of medical information obtained in private consultation They have pointed out that a practitioner's special training and knowledge enables him to draw conclusions from what he has been told, or to gather from indications facts which the patient did not wish to communicate or which were even unknown to them Where the doctor has discovered a mental or physical illness of which the patient was unaware, and has for medical reasons found it advisable to hide this knowledge, he will naturally be unwilling to divulge the information in open court To do so, French doctors maintain, would not only be contrary to the Hippocratic Oath and the professional code but would be objectionable from the scientific standpoint This attitude has been accepted by the French courts, which have held that the duty of secrecy is binding on French medical practitioners "as a duty inseparable from their calling" It is a general and absolute duty from which doctors cannot be freed, either by express order of the court or by the consent of the patient

[1] Problems of Infancy and Childhood Transactions of the T Conference March 7–8 1949 Josiah Macy Jr Foundatio New York.

Whether medical privilege of such wide scope is altogether desirable is a question on which French lawyers and medical men are still at issue It is hard to avoid the conclusion that professional privilege so widely extended must give rise to difficulties in practice, not least to litigant patients themselves But in this country, whose courts do not recognise medical privilege at all, it is certainly worth pondering over the reasons for, and implications of, French practice on medical secrecy In at least one part of the Commonwealth, the State of Victoria (Australia), the medical profession already enjoys the same professional privilege as lawyers possess under the common law

Electrical Stimulation of the Brain

THE discovery by FRITSCH and HITZIG[1] in 1870 that parts of the brain are electrically excitable raised a host of possibilities which neurophysiologists have been exploring ever since Perhaps the most valuable studies are those of Prof WILDER PENFIELD, F R S, and his successive colleagues at the Montreal Neurological Institute, because they were made on the unanæsthetised human brain The observations now summarised in book form by Professor PENFIELD and Dr RASMUSSEN[2] were made over a period of 20 years during brain operations under local anæsthesia, with their patients' intelligent coöperation In patients with focal epilepsy they have often reproduced an epileptic aura from an area of brain which is not usually susceptible to electrical stimulation They have also been remarkably successful in reproducing complex sensations by stimulating the temporal lobes, and they give many instances of psychical seizures, including complex visual or auditory hallucinations, produced in this way

Most of their work, however, has inevitably been concerned with the sensorimotor cortex, and they have many records of the local sensations resulting from stimulation of the postcentral gyrus, which cannot be studied in animals They have revised the "homunculus" published by PENFIELD and BOLDREY[3] in 1937 to show at a glance how the parts of the body are represented in the precentral and postcentral gyri In their two diagrams of the sensory and motor homunculi we see a nightmare hemi mannikin sprawling head downwards, with his foot dangling out of sight into the longitudinal fissure and the successive parts of his body varying in size according to the extent of their representation The sensory diagram brings home to one how large a share of the postcentral gyrus is taken by the hand and lips, the little finger is drawn as large as the index, and PENFIELD reminds us of the importance of sensation in the ulnar aspect of the fifth finger and hand in writing Neurologists are sometimes puzzled by his attitude to "levels" of function For example, he writes (p 235) "It seems fair to conclude that within the diencephalon there are neurone circuits which may be considered the highest level of neuronal representation and re representation" Here he seems to be using "highest level" in an entirely different sense from that which HUGHLINGS JACKSON gave it long ago Modern neurophysiology teaches that cortical mechanisms are outgrowths and elaborations of diencephalic structures These structures therefore form a vital hub for human brain activity, but they are surely more the "telephone exchange" or the "furnace' for human endeavour than a "high level" in JACKSON s sense

Curiously enough, however, the functions of the much-studied motor cortex have been the centre of most neurological controversy in recent years The experimental contraction of a single muscle by electrical stimulation of the precentral gyrus has been cited as evidence of discrete muscle representation in the motor cortex, but the clinicians have staunchly defended the view that the motor cortex must control movements rather than individual muscles LIDDELL and PHILLIPS,[4] in their paper on thresholds of cortical representation, show how these conflicting views have arisen They found that the traditional map of motor points could be reproduced in the motor cortex of the baboon by repetitive stimulation at, say, 50 cycles per sec But a stimulus consisting of a single weak "square-wave" produced an entirely different response They now found wide areas covering the whole of the motor cortex from which one of three responses could easily be obtained Far the most readily and widely elicitable was a contraction of the thumb index-minimus muscles The other two areas were concerned with hallux toe movement and secondly with tongue and face movement By demonstrating that thumb index-minimus movements can be obtained from an immensely wider cortical area than has hitherto seemed possible, this Oxford work has exposed a complexity of cortical motor function which must change and ultimately clarify our ideas of the functions of the motor cortex In stimulating the motor cortex, the physiologist is clearly "butting in" on a complex mechanism of motor patterns which we are very far from understanding

1 the serum globulin decreased and bone pain was relieved, but the marrow picture remained unchanged

Outside the reticulosis group of diseases, ACTH and cortisone have been used successfully in only two blood diseases Dameshek[6] reports that in 2 patients with idiopathic acquired hæmolytic anæmia who had not responded to splenectomy, ACTH treatment seemed to suppress the active agglutinins or hæmolysins and no further blood transfusions were needed, Gardner[7] obtained similar results in 3 patients who were given 60–100 mg ACTH daily The other condition that has been treated with ACTH is Henoch Schonlein purpura, and since this is not a true "blood disease" but a disease of blood-vessels possibly related to the collagen diseases, a response might well be expected Stefanini et al[8] reported the effect of ACTH on a boy of three who had skin purpura and intestinal affection, the child had been ill for six weeks when treatment was begun, the cutaneous lesions cleared and abdominal pains ceased within six days It is of course difficult to assess the effect of treatment in a condition so liable to spontaneous remission and Stefanini thinks that the ACTH simply relieved the vasculitis without eradicating the disease

It is thus clear that the application of ACTH and cortisone in blood diseases has produced some hopeful results, and that further studies of their effect in acute leukæmia and anaphylactoid purpuras are well justified In particular we shall look forward to learning whether, by themselves or in combination with folic acid antagonists, ACTH or cortisone offer a chance of controlling acute leukæmia

Professional Privilege Abroad

It is an ancient rule in professions that secrecy must be preserved about all facts coming to the practitioner's knowledge in the exercise of his duties But whereas members of the legal profession cannot in any circumstances be forced to divulge information entrusted to them for the purpose of obtaining advice, the law of this country does not extend protection to doctors A medical man summoned to give evidence in a court of law in any criminal or civil matter enjoys no privilege that will secure him against questions tending to elicit information, however confidential, obtained in the consulting room The law on this point was expressed in the leading case of Wheeler *v* Le Marchant (1881) as follows

> "The communications made to a medical man whose advice is sought by a patient with respect to the probable origin of the disease as to which he is consulted, and which must necessarily be made in order to enable the medical man to advise or to prescribe for the patient, are not protected "

and a textbook on modern medical jurisprudence advises members of the profession bluntly "A witness must remember that there are no medical secrets" There is no doubt that a doctor refusing to disclose confidential information in the witness box renders himself liable, if the judge is so minded, to be sent to prison for contempt of court To this state of affairs medical men have long objected, and the British Medical Association advises that "professional secrecy should be contravened only under protest after direction from the presiding judge." The law or its interpretation may yet be changed, and some light on the considerations that should guide future policy may be gained from a survey of foreign legal systems which have deliberately adopted a different attitude

In France, as elsewhere on the Continent, medical secrecy has been recognised as requiring and deserving the protection of the law No measures to maintain and improve public helath, and no health service, can, it is held, be fully effective unless the public has complete confidence in the medical profession and will invoke its help as soon as the need becomes apparent In the case of venereal diseases, for instance, experience is said to show that early attendance at a clinic can be expected only if secrecy is assured Moreover, medicine is a science which requires facts to work on, and to enable the doctor to decide what treatment is best he often needs from his patient a frank account of all the physical and mental symptoms Such a history may not be obtained unless there is a firm belief that the doctor will keep strictly to himself whatever he is told Taking it as axiomatic that unreserved communication is an essential condition of successful medical treatment, French law considers that protection against unauthorised revelations is not only indispensable to the patient but also important to the doctor and a safeguard of public health Accordingly, French law—like the law of Italy, Germany, Switzerland, and many American States—has been so framed as to place confidential medical information beyond the risk of casual disclosure, and to reconcile, as far as possible, the demand for secrecy with the needs of justice An article of the Criminal Code (art 378) renders punishable by imprisonment and fine not only medical practitioners but also pharmacists, midwives, and other related persons who without express authority reveal confidential communications made to them by patients In addition, any voluntary disclosure of such information lays a medical man open to a claim for damages at the suit of the aggrieved party—whether or not silence has been expressly imposed before the particular consultation These remedies are so clearly understood on the Continent that occasion rarely arises to enforce them, but they give doctors full sanction to refuse disclosure of confidential information, even if the demand is made in a court of law

The right to refuse to answer questions of this sort in the witness box may be of two kinds it may be absolute or it may depend on the attitude of the person most directly concerned Both systems are represented in the law as it now stands in various Continental countries German law, for instance, holds that the duty of secrecy is imposed solely for the protection of the patient Like professional privilege covering legal advisers in English courts, the privilege that can be claimed by medical men in German courts gives way, therefore, as soon as the patient releases his adviser from the duty of silence Such consent entirely destroys the justification for the doctor's refusal to speak about the privileged matter, it not only entitles the doctor to testify, but obliges him to do so even if he thinks that this is not in the true interest of his patient A similar situation prevails in most Swiss cantons The French medical profession, the age of 4 years, separation from home was the principal cause of anxiety, whereas in children aged 6–12 fear of anæsthesia was prominent. The child's reaction corresponded to the soundness of his personality structure. Furthermore, of 28 who adjusted themselves well to hospital conditions only 1 had an unsatisfactory relationship with his parents, whereas of 13 who did not adjust themselves, 10 had an unsatisfactory relationship. It was concluded that in the well-adjusted child tonsillectomy is least likely to produce psychic trauma between the ages of 5 and 10 years, and operation should be postponed if the child has suffered any recent traumatic experience. To overcome apprehension the child should be told in advance something of what to expect in hospital; this information should be given by some trusted person, usually the mother. With a 24-hour waiting-period in hospital before operation most children over 4 years of age became somewhat acclimatised, but younger children, who suffer more from separation, do not benefit from such a period.

CONTROL OF BRUCELLOSIS

Early in 1950 the World Health and Food and Agriculture Organisations (W.H.O. and F.A.O.) were asked by their member-countries to produce a plan for combating brucellosis. Their immediate response was to select a panel of experts on the disease and designate 12 centres in various countries which would stimulate research and training in field and laboratory methods. The report[1] of the panel's first meeting in Washington makes encouraging reading because it squares up to a world-wide problem. In the United States, halving the number of cattle infected with brucella has saved 50 million dollars annually, and eradication of the disease from Norway has cost less than a year's toll among farm animals. Since brucellosis does not pass from man to man the human infection can best be controlled by eradicating the disease from animals; but for this accurate diagnosis and reporting are essential. The panel recommends that all governments should make brucellosis, whether in man or in animals, a reportable disease, and it proposes a central pool of information on which all countries may draw. With probably at least 20% of British cows infected, we have a stake in this campaign, and it deserves the widest support.

As an earnest of its practical intentions the panel includes in its report an excellent account of current knowledge of the disease, though it says little on the clinical side. Brucellosis in this country means infection with *Brucella abortus*, but *Br. melitensis* has been isolated from cow's milk in some areas and we cannot dismiss the possibility that this organism may become more widespread. The report deals with modes of transmission to man, including entry through the mucous membranes and the conjunctiva and airborne spread. Modern laboratory methods of diagnosis are described, as are the newer methods of treatment, though none of these have yet proved really satisfactory. The main burden of the report bears, as it should, on brucellosis in farm animals, on the methods of diagnosing such infections, and on the production and control of strain-19 vaccine which is widely used in cattle. The panel is well aware of the variations in the method and in the antigens now used for agglutination tests and in the techniques for culturing the organism. It offers to distribute stock cultures and sera, and these should help to improve laboratory standards of diagnosis. It also describes the new ring or A.R.B. test in which a stained antigen is added to whole milk and, if positive, the antigen collects on the fat globules to give a coloured cream line. This is a fairly sensitive test and should simplify field tests on infected herds. The detailed instructions for the control of brucellosis in swine will interest the agricultural and public-health authorities in countries where *Br. suis* infections are widespread. There are many distinguished names on this international panel of experts, and the report shows that they mean to get on with the job.

CRITICS OF PSYCHO-ANALYSIS

Freud's teaching has now been widely, if thinly, spread over life in the United States, and perhaps the missionary spirit of some of its transatlantic exponents is the cause of some recent critical reactions by eminent thinkers on the Continent, where Freud came into fashion many years earlier.

Gruhle[1] attacks the philosophical validity of psycho-analytic interpretations:

> Freud says of the dream that it protects sleep. This is Freud's interpretation of its objective purpose; the dreamer knows nothing of it. Freud refers to his own observation but wrongly, for no observation can support his thesis. Freud also says the dream is wish fulfilment, an interpretation of subjective purpose again unknown to the dreamer. Freud tells him: You don't know it, but I know. This Freud calls observation; he calls observation his own experience of evidence.

Gruhle sees in psycho-analytic teaching only the enchanting play of magic, poetry, and myths, which places it outside science and scientific criticism. He warns us against drawing any conclusion from therapeutic results which may be equally achieved by all kinds of procedures and creeds, though the rational appeal in the cloak of science is probably the most effective mode of faith-healing today. He insists that Jung, for instance, persuades his patient that his dream images are of deep significance and reveal eternal truths. When the patient has been converted to this belief he thinks he has access to deep knowledge and secret meanings, and finds peace in this his own religion. According to Gruhle one has to see clearly the dividing line between the adept, who is stirred and may be deeply moved, and the sober scientist who can discover only misguided imagination.

Karl Jaspers, now professor of philosophy in Basle, was at one time a psychiatrist. His criticism[2] is distinguished by its moral undertone. He cannot find any criterion of true or false in the boundless interpretations, distortions, oppositions, and over-interpretations of everything used by psycho-analysts; there is no standard of discernibility in the infinite flux of meanings they may find. To consider illness as guilt, as Freud sometimes does, and to extend this view more or less to all diseases is, in Jasper's opinion, a wholly unmedical attitude. It leads to an inhuman philosophy contrary to the physician's ethics. Jaspers sees in some analytical writings a destructive fanatical tendency to use therapeutic methods in order to gain power over human souls. His strongest protest, however, is directed against the growing orthodoxy and intolerance of analytical societies and schools. A successful teaching analysis as the condition of full membership and of registration as an analyst becomes more and more a sacrifice of personal freedom in thinking comparable with the monastic exercises of the Jesuits or the practices of the Yogi. Jaspers has great doubts whether it is compatible with the freedom of a university in Western civilisation that the psycho-analytical institute of the university should ask its students to undergo a teaching analysis which is only declared successful if the candidate accepts the faith. His principal contention is similar to Gruhle's—that psycho-analysis, using pseudoscientific terms, claims to solve problems in human existence that science cannot solve without weakening its foundations and abandoning part of its freedom.

[2] Jaspers, K. *Nervenarzt*, 1950, 21, 465.

now used as a plasma substitute in many hospitals in this country, with apparent success It restores plasma volume satisfactorily, it remains in the circulation long enough to sustain the circulation until the amount of circulating plasma protein is again sufficient for this purpose, and so far as is known its use is unattended by unpleasant immediate or delayed effects It has certain disadvantages common to many plasma substitutes it is a substance foreign to the body and cannot be expected to perform all the functions of plasma protein, it has no buffering power, and probably no nutritive value, and though it seems to disappear slowly from the body, its fate is not known with certainty But if these shortcomings are understood and it is used with discretion, dextran has a useful part to play as a means of raising depleted blood volume, especially in emergencies when the natural fluids, blood and plasma, cannot be obtained in sufficient quantity But dextran also has other less obvious uses As a relatively inert substance, which disappears slowly from the tissues until only traces remain, and can be made in a wide range of molecular sizes, it can be employed as a tool for investigating problems such as the permeability of membranes, the properties of the reticulo endothelial system (by which dextran is taken up and from which it is gradually lost), and the behaviour of certain cell surfaces Moreover, when converted to a sulphuric ester, dextran becomes an anticoagulant On Feb 13 the Royal Society of Medicine's section of experimental medicine heard accounts of experimental work on these lines now being done at the Birmingham Medical School and by the Medical Research Council's burns unit in Birmingham

The most complete report was that of Dr KENNETH WALTON on the anticoagulant activity of dextran sulphate Dextran itself, which is uncharged, has a negligible effect on blood clotting, but the electronegatively charged sulphate exerts an antithrombin action, like that of heparin, which it structurally resembles GRONWALL et al[1] reported in 1945 that sulphuric esters of dextran acted as anticoagulants, but they did not pursue the discovery, because these esters also had undesirable effects Since inulin sulphate, which is of smaller molecular size, was even more toxic, they concluded that toxicity was unrelated to molecular size WALTON deduced from the Swedish data that the molecular weight of the toxic dextran sulphate used by GRONWALL et al was at least twice that of heparin, and he decided to examine dextran sulphates with a lower molecular weight His experiments disclosed that below a molecular weight of about 20,000 these had an anticoagulant action in animals without the toxic effects associated with esters of molecular weight 35,000 and above The latter group of substances, unlike the former, caused a precipitation of fibrinogen, agglutination of platelets, and the deposition of metachromatic staining material in the reticulo endothelial system The resulting fibrinogenopenia and thrombocytopenia explain the liability of this group of large molecular weight esters deposits in the reticulo endothelial system

The dextran sulphate finally selected at Birmingham for fuller investigation is free from these undesirable actions It can be given to animals in doses at least 100 times greater than the least effective anticoagulant dose, and it has a potency of some 17–20 I U per milligramme when assayed against the standard heparin Inactive by mouth, it can be sterilised by autoclaving without loss of potency if suitably buffered, and it has been given in doses up to 500 mg per kg body weight to mice, rats, rabbits, dogs, and monkeys without toxic effects, though the guineapig is an exception With doses of 40 mg per kg body weight, the blood pressure and pulse and respiration rates of anæsthetised dogs are unaffected, and at concentrations sufficient to produce an anticoagulant effect the alterations in erythrocyte sedimentation are negligible The dextran has not been demonstrated *histologically as metachromatic material in any of* the tissues examined, after single and repeated injections and over periods ranging from some hours to some months after injection Some 25% of the material is excreted in the urine in the first fifteen minutes after injection Its effect on clotting seems to be similar to that of heparin It will not prevent the clotting of pure fibrinogen by thrombin, unless a co factor associated with α globulin or the α lipoprotein fraction of plasma or serum is present, but in the presence of this factor it acts as an antithrombin. A clinical trial of dextran sulphate is in prospect and the results will be awaited with interest, for there is a place for a relatively cheap, effective, and uniform anticoagulant as free from undesirable actions as dextran sulphate seems to be

Dr JOHN HARDWICKE described the further progress of his investigation[2] of the effects of dextran of various molecular sizes on erythrocyte sedimentation, and Dr D B BREWER recounted experiments on the excretion of dextran by the kidney from which he hopes eventually to derive information about the size of glomerular pores Dextran is apparently excreted chiefly by filtration through the glomerulus, the tubules playing little or no part either in excretion or reabsorption

The Aged

WORK done in Birmingham to provide the basis of a coherent administrative policy for the care of the aged was described by Prof A P Thomson addressing the Manchester Medical Society on Feb 7 It had been found, he said, that three fifths of the patients in the infirmaries required neither frequent medical attention nor skilled *nursing*, and if those were the criteria for continued stay in hospital more than half the patients *now in* the infirmaries should be accommodated either in their own homes, with the help of improved social services from local authorities or voluntary agencies, or in institutions (other than hospitals) which provide domestic services and simple nursing (washing, feeding, and dressing) Of applicants for admission to the infirmaries, at least half had no need of hospital accommodation though they required help of a different kind

A C T H can also prevent the formation of a pyogenic membrane and scar tissue, and apparently it can do this even when given in a dosage below that which would inhibit all healing There is also a possibility that its lymphocytolytic action may so modify antigen antibody reactions as to prolong survival of homografts The daily dosage of the hormone (120 mg) in cases of severe burns was hoped to be not so large, or so long continued, as to cause side-effects But Converse[3] reports adverse effects on withdrawal of the hormone, and Moore[4] says that A C T H is not a panacea in burns By decreasing capillary permeability A C T H may also have a rôle in controlling the hæmorrhages of severe radiation sickness

PRIMARY LOCAL TREATMENT

Under civilian conditions local treatment in the primary phase is not of major importance, provided that the method used is clean and reversible (tanning is irreversible) The concept of the burned area as a parasite whose removal terminates the disease lends attraction to the idea of primary excision This is in fact the method of choice with localised deep contact burns such as those which may befall unconscious patients

With more diffuse burns the chief difficulties about primary excision are (1) the unreliability of early diagnosis of full thickness skin loss, and, even more, (2) the hazard to life and to the success of primary grafts, from applying this method to a burned surface of any extent (10% or more of full thickness skin loss) while the subcutaneous tissues are still firmly attached and intensely inflamed and hyperæmic At operation hæmorrhage may be profuse, and the risk is particularly great for the young and for the aged

In addition to A C T H two methods are known to limit extravasation of fluid at the site of the burn, thus helping to limit the constitutional reaction These methods are (1) cooling and (2) pressure, and local cooling is generally impracticable Local pressure has been extensively employed in America This method is time consuming and expensive in material, and except with small burns it does not prevent local fluid accumulation Applied to the neck the method is associated with irreducible hazards to life, and applied about the elbow or knee, peroneal or ulnar palsy may ensue

The main objective of local treatment is to keep the surface sterile and dry Physical protection by covering the burned area is essential for some patients—those who are being evacuated or who are not admitted to hospital, and Service casualties who must for a time remain in action Treatment would be greatly simplified by composite dressings with an intimate layer of an atraumatic fine gauze mesh supported by packed cellulose, whose outer layers were rendered water repellent by impregnation with silica, these dressings should be prefabricated into shapes and sizes to fit special parts (such as the hand or trunk) with tapes attached for secure, but not tight, fixation What is wanted is an inexpensive dressing thick enough to give some physical protection but not too thick for easy storage, it should be vapour permeable, but fluid impermeable The 'Nylon' derivative dressing, which has been tried extensively does not seem to be sufficiently permeable to water vapour to prevent maceration when it is applied over a fluid producing lesion An ideal dressing should make it possible to combine the first aid and the definitive local primary treatment of all burns

It is not necessary to cover the burned skin to obtain local dryness and sterility Indeed there is much evidence that for hospital patients simple exposure of the area is the best, as well as the cheapest, means of obtaining these conditions and so limiting the complications of infection (secondary skin loss and constitutional reactions) DeVirginia Blocker has reminded us that the exposure method was once widely practised in America, Copeland[5] first described its use in 1887, and Halder Sneve[6] underlined its practical advantages in 1905 Ten years later Haas[7] remarked exposure "is an ancient method quite ancient enough to be new" We owe it to A B Wallace, of Edinburgh, that this method has been reinvestigated and its full value established This is possibly the best of all local primary treatment for burns of the perineum and face in children, and of the face in adults—that is, in sites where soiling of dressings is difficult to avoid

Exposure is always a hospital procedure, it should be combined with early immobilisation of the part in the position of function, since cracks in the coagulum may lead to infection The burn can be exposed at any stage to ward atmosphere Circumferential trunk burns are unsuitable for exposure unless the patients are ambulatory, because body pressure or friction of sheets on the coagulum may lead to infection With exposure there forms a flexible coagulum, this is apparently free of the tourniquet dangers of tanning, but it is slow to separate Superficial burns treated by exposure are a week to ten days slower in healing than similar burns treated with tulle gras, and often it takes longer to ascertain the depth of the burn when the area is dry

What local treatment should be given in addition to exposure or absorptive dressings is debatable Most workers agree with Pulaski that lavage with a detergent is desirable Truman Blocker in Texas, however, often leaves the burned surface exposed without preliminary toilet and the incidence of early infection in his cases is certainly very low Penicillin cream has the disadvantages that an increasing proportion of patients are sensitive to it, its activity does not continue long enough to give security from infection of the sterilised burned surface from deeper layers of skin or from marginal areas, during the week or more that the first dressing should be left undisturbed, and its semi fluid composition encourages maceration Pulaski[8] has shown that penicillin carbonate by mouth provides adequate blood-penicillin levels for most patients, and it seems that this will more certainly sterilise the deeper layers of a burn than will topical penicillin

The risk of tetanus in burns was mentioned by Dupuytren over a hundred years ago, but has since often been overlooked Altemeier[1] recently reported an incidence of contamination by tetanus organisms of 3% in routine smears from primary burns Anti tetanus serum should certainly be given in all cases, and the advisability of active immunisation of the whole population should be seriously considered

TREATMENT IN THE HEALING PHASE

It is on the surgical programme in the healing phase, and only rarely on faults in local primary care, that the prognosis in deep burns depends after the second week The negative nitrogen and electrolyte balances, the disturbances of endocrine function, and the profound and resistant anæmia seen in the healing phase are all chiefly caused by the presence of dead tissue, or from the later persistence of granulations uncovered by skin I have suggested that primary excision of burns should not be practised routinely, but equally in the healing phase the removal of sloughs and the provision of a fresh skin surface should not be unduly delayed The vegetable collagenase described by Altemeier holds great promise, but this and other enzymic debridement agents are still at the

BURNS

A REVIEW OF THEIR MANAGEMENT

PATRICK CLARKSON
M B E , M B Lond , F R C S
CASUALTY SURGEON, GUY'S HOSPITAL, LONDON

IN the past the treatment of burns has not always reflected credit on the medical profession , for the issues have too often been debated with emotion rather than detached judgment True, mortality and morbidity have steadily fallen in the past thirty years , but even quite lately the profession has sponsored the local application of tannic acid despite its very harmful effects, and probably many patients have died needlessly because of excessive and protracted administration of fluid intravenously

The urgent topicality with which modern weapons have invested the subject of burns is illustrated by the symposium held last year in Washington,[1] by the meeting on Feb 9 of the United Services' section of the Royal Society of Medicine, and by a number of publications—notably one by Colebrook [2]

THE PROBLEMS OUTLINED

An extensive deep burn has a natural clinical course in three overlapping phases The primary phase of shock and counter shock lasts up to ten days and results in either exhaustion or survival It may be followed by the second, or healing, phase, which is of indefinite length depending on the depth, size, site, and treatment of the raw areas , this phase, in which dead tissues separate and the raw areas are re surfaced, is often characterised by profound metabolic disturbances and anæmia When re surfacing is complete there follows the third phase, in which attention turns to rehabilitation or to reconstructive surgery

In the primary phase the objects of treatment are, briefly, to preserve life by maintaining the circulation, and to prevent infection Maintenance of the circulation involves (1) restoring water, electrolyte, and colloid balance by administering fluids , and (2) attempting to control the humoral factors in this mechanism by dialysis or by administering hormones, such as the adreno corticotropic hormone (A C T H) The prevention of infection is chiefly a matter of local primary care If this is adequate, superficial burns heal without residual disability by the second or third week , and the deeper burns are then ready for surgical treatment in the healing phase In this phase treatment consists in removing dead tissues and re surfacing the raw areas by healing techniques, combined with measures to correct the metabolic disorders and anæmia

Today the possibility of war time atomic explosions and of burns from jellied petrol or from flame throwers poses additional problems These include the effects of simultaneous exposure to ionising and thermal radiations , the effects on the lung of inhaling hot air or steam , the effects on heart and brain of acute hyperthermia , the effect on mortality of impaired renal function , and the relation of depth of burn to early mortality, particularly where there is heat coagulation of muscle With regard to these war time risks, the need is, not to discover the ideal treatment, but to decide what is practicable In other words, what can best be planned for mass casualties ?

FLUID, ELECTROLYTE, AND COLLOID BALANCE

The question of fluid, electrolyte, and colloid balance in the primary phase has been reinvestigated by isotope techniques The need for careful control is emphasised by Cope, Moore, Pennell, and others,[1] who sharply restrict the amount of fluids administered intravenously once the local capillary permeability has returned to normal and diuresis has started—which is usually about the end of the second day

The main therapeutic index is still the percentage of body-surface burned—i e , replacement therapy is based on the calculated extravascular loss of the fluid, salt, and colloid constituents of the blood A formula commonly used for this purpose is 1–3 ml of fluid per 1% body surface burned per kg body weight on the first day, and 1–2 ml per 1% per kg on the second day Probably however, an empirical scale, decided rather by the response of the blood pressure and the urinary output, provides better for the individual patient's needs Whichever method is followed, the amount administered to adults should rarely exceed 3000 ml each of colloid and electrolyte solutions intravenously, plus 2000 ml. of water by mouth, during each of the first two days commonly more is given in the first twenty four hours when the need is more urgent, than in the second When oliguria is replaced by diuresis, restriction of fluids is very necessary, to avert the risk of fatal pulmonary œdema The optimum electrolyte solution varies in different patients, and sometimes from time to time in the same patient Under ideal conditions repeated estimations of the blood content of sodium, potassium, and chloride should be done if the risk of serious electrolyte depletion or intoxication is to be avoided

The colloid fluids of choice are blood and plasma Cope[1] has, however, reminded us that these have a higher protein content than has blister fluid, and therefore they may not be ideal Blood transfusions in the first forty eight hours seem to delay and reduce the anæmia of the healing phase In planning for mass casualties plasma substitutes have an important place , and the substitutes that have been most widely investigated are gelatin, globin, and dextran Both Ravdin and Everett Evans[1] report favourably on gelatin, they used the Knox P20 preparation—a relatively homogeneous molecular solution of a degraded ossein gelatin Strumia[1] points to the value of globin, which affords the only means of salvaging red blood cells in stale stored blood Both gelatin and globin are protein substitutes for a protein loss, and are at least partly metabolised by the body Dextran, on the other hand, is a polysaccharide , but there is a good deal of evidence of its effectiveness as a short term plasma substitute (Bull and Thorsen[1]) It dilutes the plasma protein, affects the blood sedimentation rate, gives rise to occasional reactions, and by causing rouleaux formation makes blood grouping difficult Its fate in the body is not fully understood , it is still expensive We need to know more about its polymer chemistry and its metabolism before pressing for its general adoption as a plasma substitute.

The value of dialysis by the artificial kidney in the oliguric phase of patients with impaired renal function has been investigated by Thorn and Moore, who have shown that in the primary phase this procedure may remove from the circulation depressor substances secreted by the liver as well as excess water and electrolytes

Of the other humoral factors concerned in this aspect of the primary phase, the most important is A C T H This seems to block the body's reaction to injury Its possible effects, in addition to an anti hyaluronidase action, which limits early capillary permeability, include reduction of histamine synthesis and suppression of the early constitutional reactions, such as pyrexia, tachycardia, and malaise Even with burns of 40–60% of the body surface, administration of this hormone may permit ambulation and full sleep, with appetite for food, from the first day , and its gluconeogenic action helps to protect liver proteins Later, during the healing phase, about the need for specialists in reaching diagnoses, but perhaps the best way of judging their value is to consider certain notoriously difficult diagnostic situations which nevertheless *can* yield some sort of definite solution.

[1] See *Lancet* 1950 ii 635
[2] Colebrook, L A New Approach to the Treatment of Burns and Scalds London 1950

Any middle aged or old person with a chest illness which does not rapidly clear up must be considered a cancer suspect. But to determine whether or not he has cancer may be very hard. The plain chest X ray film may merely reveal an indeterminate shadow, and the sputum examination a mixed growth of common organisms and no malignant cells; the lesion may be out of reach of the bronchoscope, and the bronchogram findings may be equivocal. One may therefore ask whether a physician who spent all his time in dealing with patients affected by chest diseases would be more likely to reach the right diagnosis than the general physician. It seems highly doubtful whether he would be appreciably more successful. And since precise diagnosis is here impossible, the correct attitude to adopt is either to recommend exploration of the chest or to admit doubt until unequivocal evidence pointing to cancer or benign inflammatory disease develops. It is equally doubtful whether the chest physician would be superior to the general physician in deciding whether to refer the case to a thoracic surgeon (in whose hands the final decision as to chest exploration must rest) or to await developments.

A similar situation is provided by many subjects with acute intra abdominal disease. No one can be sure of the diagnosis, and the best that can be said of the specialist surgeon by comparison with the sound general practitioner is that his guess will turn out correct more frequently. Here the important practical questions to be asked are not the finer points of diagnosis but: should a laparotomy be done? and, if it should, where should the incision be made? It is doubtful whether the specialist would give markedly superior answers to these questions. Indeed, it is extremely difficult to say in retrospect, when the patient is either dead or better, what was the correct answer to the first question; for the laparotomy which did not help the patient may still have been a wise precaution, and the failure to operate which was *not* followed by the patient's death may still have been an unjustifiable risk.

One may next ask how the specialist and the general physician compare in their ability to label obscure syndromes which cannot usually be given confident ætiological diagnoses. The case of "brachial neuralgia" may be taken here. Subjects so affected may be labelled very differently by different physicians, while fashions in diagnosis have come and gone in recent years and have included "true neuritis," vitamin B_1 deficiency, cervical rib, septic tooth sockets, and prolapsed cervical intervertebral disc. In the light of existing knowledge, probably the soundest attitude towards at least many cases of "brachial neuralgia" is to admit that beyond this label no diagnosis can be made. The general physician will be more likely to adopt this modest view than the physical medicine specialist or even, perhaps, the neurologist.

The field of rarities provides examples in which several doctors may be quite in the dark, while another confidently, and correctly, makes a diagnosis on purely clinical grounds. In these circumstances the supremely important aid to diagnosis is previous personal experience of the particular syndrome in question. Here the specialist will as a rule have a clear advantage over the general physician, unless the syndrome is some general disturbance claimed by no specialty. But such circumstances are very rare. They seem much commoner than they are because they provide opportunities for startling diagnostic tours de force which may be remembered and admired in medical schools for many years. The story is sometimes heard of a great clinical giant, long since dead, who entered a ward, looked fixedly at a sick man, felt his pulse and studied his tongue, made a few dramatic gestures, and then boldly announced to his astonished clerks that the diagnosis was X's syndrome—a diagnosis triumphantly verified post mortem.

The specialist may be in a much more favourable position than the general physician when the practice of his specialty involves a knowledge of some difficult technique. In the case of "? simple ulcer, ? carcinoma of the stomach" which is being studied clinically and radiologically, the gastro enterologist would probably not guess right any more often than the general physician. But if the former is an expert gastroscopist he may sometimes be able to reach a confident diagnosis. Similarly, when studying conditions of the large bowel, the expert with the sigmoidoscope will give a better opinion than the physician who has rarely used that instrument. Nevertheless, leaving aside ear, nose, and throat, eye, neurosurgical, and perhaps genito urinary specialists, such special techniques carried out by the clinician himself do not, as a rule, play a very important part in reaching diagnoses. In so far as special studies are required, X rays, blood counts, microscopical and cultural examinations of the urine, determination of blood chemistry figures, and others not normally undertaken by clinicians are generally far more important. Admittedly, the clinician should study X ray films himself, and not merely accept the radiologist's opinion. This conclusion is especially true of chest radiographs; and here the chest specialist may be a little more accurate than the general physician in the doubtful case. In respect of the other tests mentioned, the clinician merely has to interpret figures; and that feat should almost always be performed as accurately by the non specialist as by the specialist.

In the narrow diagnostic field of determining the nature of the lesion, the specialist, then, is as a rule markedly superior to the general physician only when the mastery of some special technique is necessary.

DIAGNOSIS IN THE BROAD SENSE

It was said above that, whereas in the diagnosis of the acutely sick the only relevant question is as a rule "what is the exact nature of the lesion?" in diagnosing the chronically sick it may also be necessary to ask one or more of the following three questions:

1. Is a significant organic lesion present?
2. If such a lesion is present, are the symptoms at all due to it?
3. If the answer to question 2 is Yes, to what extent should the symptoms be ascribed to the lesion and to what extent to the state of mind?

Errors in answering all these questions are extremely common. Patients who are in fact free of organic disorder may be given such labels as strained heart, myocarditis, intestinal auto intoxication, and early hyperthyroidism. The symptoms are often ascribed wrongly to astigmatism, retroverted uterus, deflected nasal septum, visceroptosis, gastritis, hypertension, and innumerable other conditions. It is widely assumed that all the symptoms have an organic basis whereas in fact they are largely of psychological origin. This mistake is typically made in the case of those with well compensated heart lesions.

Such wholly wrong diagnoses as strained heart and myocarditis are perhaps usually made by general practitioners. But the wrong ascription of symptoms to astigmatism and other similar disorders is particularly a specialist's mistake. The general physician faced with experimental stage With most deep burns in adults the dead tissue has to be excised by knife and scissors (when possible under a tourniquet) This should be done in the second, or early in the third, week At this stage the raw area so exposed is very receptive to a free graft cover, which is best applied at the operation for slough removal, but if oozing is excessive, or the area large, it may be delayed two to four days With refrigeration of skin grafts[9] these procedures can easily be staged the skin may be applied later without anæsthetic The electric dermatome has greatly simplified the problem of cutting grafts and has made it more often possible to provide cover with continuous sheets of split skin grafts rather than with discontinuous patches The surgical programme for deep burns should be arranged so that the raw area substantially healed within a month of the burn Some very extensively burnt patients, and the very young and very old, have to be handled at a slower pace, but rarely is there any good reason for deferring slough excision and completion of the primary skin graft cover beyond eight to twelve weeks, however extensive the burn

The *management of cases admitted with* granulations already present has become more radical[8,10] It is neither necessary nor desirable to continue dressings and cultures in order to obtain the ideal of bacterial sterility before surgery, for then, apart from the expense in materials and in labour, the graft is deposited on a fibrous base thicker than it need, or should, be for stability In the last seven years surgeons, with the combined benefits of antibiotics and of blood for replacement therapy, have tended increasingly *to excise forthwith* the whole granulating area down to unaffected deep tissues, thus providing a soft clean base for immediate cover by graft or flap[8,10]

Points of View

SPECIALISATION

JOHN W TODD
M.D Lond, M R C.P
CONSULTANT PHYSICIAN, FARNHAM HOSPITAL, SURREY

OF late years a steadily increasing proportion of young doctors have become specialists rather than general practitioners or, in the old sense of the term, consultants The *number of recognised specialties has also greatly* increased In the last century there were merely physicians, surgeons, ophthalmologists, ear, nose, and throat surgeons, dermatologists, obstetricians, alienists and perhaps a few others There are now in addition radiologists, radiotherapists, orthopædic surgeons, neuro surgeons, thoracic surgeons, faciomaxillary surgeons, neurologists, cardiologists, endocrinologists, gastro enterologists, psycho analysts, venereologists, anæs thetists, physiotherapists, and many more The patient who attends hospital may be seen not by one doctor but by a whole series of specialists, each of whom provides a report about the state of the particular region in whose study he is an expert It has even been suggested, *especially in America, that general practice* as it is now known is obsolescent and that a system of "group practice," each member of the group being a specialist, should take its place The patient would then have not his own doctor but his own group, the appropriate member of which would be summoned, according to the nature of the symptoms

With these changes specialism has acquired a heightened prestige The name specialist possesses a glamour which appeals alike to the young doctor and to the layman Probably few medical students now begin their studies intending to go into general practice, and they are apt to develop a contempt for the unfortunate G P, whose errors may be pointed out so disparagingly by clever young registrars and housemen (though perhaps with the admission that he should be more pitied than condemned, lacking as he does X rays and other facilities necessary to modern scientific medicine) After qualification, only those who fail, through lack of brains, luck, *money, or influence, to become specialists regretfully* fall back on to general practice The knowledgeable layman, who reads of the elaborate new machines needed for diagnosis, may concede that his old G P is well able to deal with a cold in the head or a bout of indigestion, but will insist *that for a serious complaint a specialist* is clearly necessary "After all," it may be said in excuse for the G P's failings, "he can't be expected to know as much about the heart as the heart specialist who has spent half his life in a close study of the disorders of that organ" A recent radio serial (*The Malindens) contains a poignant scene in* which an old man on his death bed sadly tells his daughter that his life has been a failure, because he aspired to be a surgeon but only became a general practitioner

In Britain, according to many observers, the new National Health Service has accentuated the decline of general practice and the advance of specialism, by making the lives of G P's even more harassing, while providing a large and certain income for young specialists with hospital appointments as consultants

The Specialist and Diagnosis

The immediate object of diagnosis is, as a rule, to explain the patient's symptoms Now, the symptoms *can never be wholly explained by a single* organic cause, the state of mind must also be taken into consideration The degree of pain felt by an injured man does not depend on the nature of his injury alone If he is of sensitive temperament he may suffer great pain, if he is phlegmatic and unimaginative his pain may be slight When diagnosing the acutely sick it may nevertheless be correct to leave psychological considerations out of account For example, it is of small moment from the diagnostic (though perhaps not from the therapeutic) standpoint that a man's highly sensitive temperament causes him to describe the pain of a whitlow as overwhelmingly severe But the symptoms of many of those with chronic organic lesions should be ascribed far less to the lesion itself than to the state of mind, to ignore the latter is a grave mistake Moreover, symptomless organic disorders are commonly associated with symptoms whose origin is wholly to be sought in the mind In diagnosing the chronically sick, therefore, the following four questions may each need to be answered

1 Is a significant organic lesion present ?

2 If such a lesion is *present* are the symptoms at all due to it ?

3 If the answer to question 2 is Yes, to what ex*tent should* the symptoms be ascribed to the lesion and to what extent to the state of mind ?

4 What is the exact nature of the lesion ?

In the study of the acutely sick only the fourth question is usually relevant

DIAGNOSIS IN THE NARROW SENSE

The process of reaching diagnoses in the narrow sense of discovering the nature of the lesion presents greatly differing problems In some cases a complete and satisfactory diagnosis can easily be reached, in others nothing better than a descriptive label can ever be given It is therefore very difficult to generalise

Similar considerations apply to other conditions whose treatment is apparently complicated, such as peptic ulcer, congestive heart failure, and rheumatoid arthritis One gastro enterologist will treat a peptic ulcer patient with prolonged rest in bed, no smoking, two hourly feeds of citrated milk and no other food, olive oil, belladonna, and mag carb co thrice daily, another will treat an identical case with a diet from which little is forbidden but which is taken at frequent intervals, will give no olive oil or belladonna, will allow smoking, and will encourage the patient to remain up and about One physical medicine specialist will order a victim of rheumatoid arthritis to bed for weeks and give him in turn short wave diathermy, massage, wax baths, and gold injections, another who practises in a spa will keep a similar patient out of bed throughout and give him warm baths, the appropriate saline drinks, and vaccines derived from organisms in the stools, and will eradicate his septic foci Indeed, in respect of diet, régime, and other general forms of treatment, the greatest experts notoriously disagree with each other at any one time, while the experts of today disagree even more violently with the teachings of the experts of yesterday

It seems absurd to pretend, therefore, that *because* a man is a specialist in some disease, his opinion as to the value of one of these general remedies for this disease is superior to that of the general physician The one form of medical treatment on whose merits there is wide spread agreement among all the experts is specific drugs, and it could not be pretended that a specialist is necessary to order them

Elsewhere[1] I advanced the view that most patients should be given simple psychotherapy, in the shape of an explanation of their symptoms, reassurance, and encouragement Clearly such psychotherapy does not require the services of a specialist in some bodily region, and still less need a psychiatrist be called in to reassure a patient who has a fear of cancer or other similar worry But psychotherapy of this kind is commonly omitted, and if it is given, it may consist in nothing more than a brusque statement to the effect that nothing serious has been found, the physician making no attempt either to discover whether the patient has some particular worry which can be eased or to tell him why he has his symptoms The specialist, so often wrapped up in the minutiæ of the system to which he devotes his life, is more apt to fail here than is the general physician For example, the cardiologist faced with the patient who complains of palpitation, weakness, giddiness, and the usual emotional symptoms, may correctly say that the heart is *organically normal*, but he may easily fail to discover that the patient's father died a sudden cardiac death at the age the patient has now attained, and he may fail to explain that such symptoms are merely the manifestations of a nervous temperament In consequence the patient may be unconvinced that his heart is normal and continue to fear that he will share his father's fate It has already been noted that the specialist is particularly liable to ascribe all the symptoms to some organic lesion affecting his own system, when in fact they are largely of psychological origin In so far as he does this, so will he omit the psychotherapy which can often minimise the disability of those with organic diseases

The Specialist and Research

Specialism is sometimes defended on the ground that without it progress in medicine could hardly occur The doctor who only sees an occasional example of some disease can rarely reach useful conclusions about its ætiology, pathology, natural history, and treatment Advances in such knowledge have often been made by painstaking workers in hospitals who collected cases of the disease and then subjected them to a careful inquiry, investigated them thoroughly, treated them with some new specific drug by the alternate case method, or followed them up over the course of years Moreover, as Cohen[2] has pointed out, in some fields “ specialisation in research is perhaps inevitable because of the intricacy of many of the modern instruments of research, e g, the electron microscope, special methods of histopathology and bacterial culture or spectroscopic analysis ”

But even the most fervid advocates of specialism would not say that clinicians should be subdivided into disseminated sclerosis specialists, heart block specialists, varicellologists, ulcerative colitologists, and so forth And equally it could not be pretended that the young man who is keen on research should devote the whole or many years of his life to doing nothing else but studying a single disease The clinical research worker, for the sake of his enthusiasm, sanity, and judgment, should clearly do something besides his particular investigation

The following question therefore arises is the specialist in a certain region any better able than the general physician to carry out a research into a single disease affecting that region ? For example, if a neurologist and a general physician both spent, say, a third of their time for a period of ten years in seeking the cause of disseminated sclerosis, is there any reason to suppose that the former would be more successful ? Or would a cardiologist who followed up a large number of patients with rheumatic heart disease for half his life reach nearer the truth than the general physician who did the same ? There is no apparent reason for giving an affirmative answer to such questions as these The necessity of special studies for the purpose of advancing knowledge provides no justification for specialisation in the ordinary meaning of that term

The Legitimate Medical Specialties

Although (if my arguments are sound) the main justification for specialisation among clinicians is the necessity for mastering difficult surgical techniques, there are nevertheless perhaps a few legitimate specialties inside medicine An obvious example is pædiatrics, for it cannot be objected that a pædiatrician is encouraged to devote his whole interest to some small region of the body, or that through following his specialty he is liable to develop a distorted viewpoint And the problems presented by infants and very young children are undoubtedly very different from those presented by adults It may nevertheless be wondered whether even here the physician who spends all his time among children is likely to be better than the physician who also deals with adults A similar “ defence ” may be made of geriatrics—a specialty of which more and more has been heard of late But the justification for geriatrics is far less than for pædiatrics There are few if any diseases peculiar to old people For example, non fatal strokes leaving paralysis, which provide one of the most common and difficult problems of old age, are seen occasionally in people below 50 and quite often in the under 60s And one often sees men in the 80s who are vigorous in mind and body while others in their 60s are living a vegetative existence It is sometimes suggested that special wards should be set aside for geriatric cases But is it not far better for old men with the more acute and recoverable conditions—and it is they who should be given most consideration—to share wards with the young ? Is not the atmosphere thereby improved, and are they not thereby encouraged to recover ? I believe too that, in spite of the “ write a patient complaining of a feeling of pressure on top of the head would probably conclude that no organic diagnosis could be made But if the patient chanced to have half a dioptre of astigmatism in one eye, or an opaque antrum in the radiograph, an ophthalmologist or otorhinolaryngologist might easily reach the erroneous conclusions that these conditions were the cause of the headache Similarly, few but gynæcologists would deduce that chronic low backache was due to a retroverted uterus, and few but gastro enterologists who possessed gastroscopes would attribute vague dyspepsia to chronic hypertrophic gastritis The third and more subtle error of ascribing symptoms wholly to organic disease when in fact they are partly or largely of psychological origin is also characteristically made by the specialist The cardiologist, for instance, with his attention fixed on the murmurs, the blood pressure readings, the pulse, the radiological appearances of the heart, and the fascinating defects in the electrocardiogram, may assume that a patient's dyspnœa and palpitation are wholly due to rheumatic heart disease when in fact they are predominantly emotional

Errors such as these are often not recognised, and a doctor may perpetrate them over and over again in the course of years and never realise that he has made a mistake The essential reason for making them is the widespread inability to see the whole patient in proper perspective, for too many doctors, and particularly specialists, are only aware of a *conglomeration of organs* facing them across the consulting room table It is sometimes said of a man who has been appointed to a hospital as a general physician that "he isn't interested in stomachs, chests, and nerves, but only in hearts and kidneys" These words are a grave indictment, for they imply that he cannot be interested in people, but only *in certain bits of their bodies*

The Specialist and Treatment

SURGERY

The ordinary practitioner cannot master every detail of surgical technique Even the whole time surgeon cannot become proficient in the performance of every operation in every region of the body The fact that a surgeon is exceedingly skilful in doing a prostatectomy provides no evidence that he can efficiently excise a pituitary tumour And the simplest operations may be carried out very badly by experts in some branch of major surgery The master of gastrectomy may admit that when a patient requires an intravenous saline infusion, his house surgeon can give it better than he can himself

In surgery, therefore, specialisation is desirable—even the ultraspecialisation which has been so often condemned in recent years The general surgeon who is willing to tackle everything—and even more the general practitioner who is willing to do the same—are rightly obsolescent figures If further difficult surgical techniques are elaborated in the future, surgical specialisation of a degree even greater than that usual now may become justified

But in that part of surgery which is at least as important as the actual technical procedure—i e, the selection of cases for operation *and the selection of the appropriate* operation for the particular case—the situation is very different The fact that a surgeon can brilliantly perform a gastrectomy is no reason for supposing that he will select the cases most suitable for this operation And of the factors which should determine whether an operation is indicated, a study of the diseased region (*in which the specialist may be most proficient*) is often not the most important For example, in deciding whether herniorrhaphy should be done, the patient's age, build, and occupation, whether he has a cough, and his personal wishes may all rightly be taken into consideration, in addition to the local condition Sometimes a most important factor in determining the need for surgery is the patient's state of mind This may be so in the case of torn internal cartilage of the knee, for the subject of sound personality who strives to recover, persevere with his exercises, and ignores his pain makes far better progress than the weak willed dullard with a *similarly damaged* knee who is satisfied *to remain a semi invalid*

In the ability to see all these factors in the right perspective, *the specialist surgeon, so far from* being superior, may be much inferior to the non specialist The very fact that he is an expert on some small region of the body tends to make him reach his conclusions from a study of this region alone There is, moreover, a natural tendency to exaggerate the importance of operations in one's own territory

An important reason why operations are wrongly done lies in the error previously discussed of making wrong diagnoses in the broad sense of improperly relating some lesion to the symptoms The *otorhinolaryngologist* may be right in saying that an antrum is infected, but is wrong in performing antrostomy, when the infection is not the cause of the headache of which the patient complains Or the neurovascular surgeon may do an extensive sympathectomy on a patient whom he rightly deems to have hypertension The blood pressure consequently falls, but the patient is no better, because his symptoms were not caused by the hypertension This sort of error is particularly made by the specialist

MEDICINE

Considerations such as these have no relevance to the physician, except in so far as he performs such surgical procedures as inducing artificial pneumothoraces Giving his remedies—drugs, régimes, diets, and psychotherapy—involves no technical skill Moreover, provided the diagnosis is correct, *any newly qualified* house physician can prescribe the drugs specific against infections just as well as can the highly experienced specialist, and such drugs provide the most striking triumphs of therapy Yet one encounters the notion that the treatment of those sick of certain conditions is difficult because of its complexity, and therefore that the specialist may succeed *better than the general physician* One such condition is diabetes mellitus

One diabetician will admit the newly diagnosed case of severe diabetes to a ward staffed by sisters and dietitians with long experience of looking after diabetics, for the purpose of "stabilisation" A dietary prescription containing the exact quantities of carbohydrate, fat, and protein is written, and afterwards at each meal a neat tray arrives from the diet kitchen on which are several aluminium dishes each containing the appropriate *amount of some basic* foodstuff Should the patient ask for more, his plea will be refused The insulin dosage will then be raised until the state of "stabilisation" has been achieved, as proved by the absence of sugar from all or nearly all the urine specimens On being discharged the patient will be provided with a scale, on which all his food except perhaps green vegetables *and* fruit has to be weighed, and a long diet-sheet giving details of the quantities of each foodstuff he should eat at each meal He is naturally profoundly depressed at the prospect before him Subsequently he attends the clinic and has *to be* "re stabilised" as he develops frequent hypoglycæmic attacks But another diabetician will utterly condemn a scheme of the kind just described He will keep such a patient out of hospital altogether (unless he is *ketotic*) and tell him to continue to eat his normal diet while increasing his insulin until his symptoms have gone

Similar considerations apply to other conditions whose treatment is apparently complicated, such as peptic ulcer congestive heart failure, and rheumatoid arthritis One gastro enterologist will treat a peptic ulcer patient with prolonged rest in bed, no smoking, two hourly feeds of citrated milk and no other food, olive oil, belladonna, and mag carb co thrice daily, another will treat an identical case with a diet from which little is forbidden but which is taken at frequent intervals, will give no olive oil or belladonna, will allow smoking, and will encourage the patient to remain up and about One physical medicine specialist will order a victim of rheumatoid arthritis to bed for weeks and give him in turn short wave diathermy, massage, wax baths, and gold injections, another who practises in a spa will keep a similar patient out of bed throughout and give him warm baths, the appropriate saline drinks, and vaccines derived from organisms in the stools, and will eradicate his septic foci Indeed, in respect of diet, régime, and other general forms of treatment, the greatest experts notoriously disagree with each other at any one time, while the experts of today disagree even more violently with the teachings of the experts of yesterday

It seems absurd to pretend, therefore, that *because* a man is a specialist in some disease, his opinion as to the value of one of these general remedies for this disease is superior to that of the general physician The one form of medical treatment on whose merits there is wide spread agreement among all the experts is specific drugs, and it could not be pretended that a specialist is necessary to order them

Elsewhere[1] I advanced the view that most patients should be given simple psychotherapy, in the shape of an explanation of their symptoms, reassurance, and encouragement Clearly such psychotherapy does not require the services of a specialist in some bodily region, and still less need a psychiatrist be called in to reassure a patient who has a fear of cancer or other similar worry But psychotherapy of this kind is commonly omitted, and if it is given, it may consist in nothing more than a brusque statement to the effect that nothing serious has been found, the physician making no attempt either to discover whether the patient has some particular worry which can be eased or to tell him why he has his symptoms The specialist, so often wrapped up in the minutiæ of the system to which he devotes his life, is more apt to fail here than is the general physician For example, the cardiologist faced with the patient who complains of palpitation, weakness, giddiness, and the usual emotional symptoms, may correctly say that the heart is organically normal, but he may easily fail to discover that the patient's father died a sudden cardiac death at the age the patient has now attained, and he may fail to explain that such symptoms are merely the manifestations of a nervous temperament In consequence the patient may be unconvinced that his heart is normal and continue to fear that he will share his father's fate It has already been noted that the specialist is particularly liable to ascribe all the symptoms to some organic lesion affecting his own system, when in fact they are largely of psychological origin In so far as he does this, so will he omit the psychotherapy which can often minimise the disability of those with organic diseases

The Specialist and Research

Specialism is sometimes defended on the ground that without it progress in medicine could hardly occur The doctor who only sees an occasional example of some disease can rarely reach useful conclusions about its ætiology pathology, natural history, and treatment Advances in such knowledge have often been made by painstaking workers in hospitals who collected cases of the disease and then subjected them to a careful inquiry, investigated them thoroughly, treated them with some new specific drug by the alternate case method, or followed them up over the course of years Moreover, as Cohen[2] has pointed out, in some fields "specialisation in research is perhaps inevitable because of the intricacy of many of the modern instruments of research, e g, the electron microscope, special methods of histopathology and bacterial culture or spectroscopic analysis"

But even the most fervid advocates of specialism would not say that clinicians should be subdivided into disseminated sclerosis specialists, heart block specialists, varicellologists, ulcerative colitologists, and so forth. And equally it could not be pretended that the young man who is keen on research should devote the whole or many years of his life to doing nothing else but studying a single disease The clinical research worker, for the sake of his enthusiasm, sanity, and judgment, should clearly do something besides his particular investigation

The following question therefore arises is the specialist in a certain region any better able than the general physician to carry out a research into a single disease affecting that region ? For example, if a neurologist and a general physician both spent, say, a third of their time for a period of ten years in seeking the cause of disseminated sclerosis, is there any reason to suppose that the former would be more successful ? Or would a cardiologist who followed up a large number of patients with rheumatic heart disease for half his life reach nearer the truth than the general physician who did the same ? There is no apparent reason for giving an affirmative answer to such questions as these The necessity of special studies for the purpose of advancing knowledge provides no justification for specialisation in the ordinary meaning of that term

The Legitimate Medical Specialties

Although (if my arguments are sound) the main justification for specialisation among clinicians is the necessity for mastering difficult surgical techniques, there are nevertheless perhaps a few legitimate specialties inside medicine An obvious example is pædiatrics, for it cannot be objected that a pædiatrician is encouraged to devote his whole interest to some small region of the body, or that through following his specialty he is liable to develop a distorted viewpoint And the problems presented by infants and very young children are undoubtedly very different from those presented by adults It may nevertheless be wondered whether even here the physician who spends all his time among children is likely to be better than the physician who also deals with adults A similar "defence" may be made of geriatrics—a specialty of which more and more has been heard of late But the justification for geriatrics is far less than for pædiatrics There are few if any diseases peculiar to old people For example, non fatal strokes leaving paralysis, which provide one of the most common and difficult problems of old age, are seen occasionally in people below 50 and quite often in the under 60s And one often sees men in the 80s who are vigorous in mind and body while others in their 60s are living a vegetative existence It is sometimes suggested that special wards should be set aside for geriatric cases But is it not far better for old men with the more acute and recoverable conditions—and it is they who should be given most consideration—to share wards with the young ? Is not the atmosphere thereby improved, and are they not thereby encouraged to recover ? I believe too that, in spite of the "write up" which geriatrics has recently had, it may be depressing to deal with none but the old, and that the physician who has patients of all ages is likely to handle his old patients better than the specialist geriatrician

---

[1] Todd J W Rational Medicine Bristol 1949

[2] Cohen H *Proc R Soc Med* 1949 42 1035

Of the other medical specialties, perhaps dermatology is the easiest to justify, for the diseases of the skin form a genuinely distinct group which are comparatively rarely related to other bodily diseases The dermatologist, moreover, can hardly reach the wrong conclusion that a patient with obscure symptoms has a skin condition, and he must be extraordinarily blind to overlook the psychiatric aspects of skin diseases, for it is obvious that they may have a disastrous effect on the psyche, while sometimes emotional and hysterical disorders are apparently important in their ætiology

Another possibly legitimate specialty is neurology Certain diseases of the nervous system cause manifestations whose assessment and analysis requires much practice and an intimate knowledge of the anatomy and physiology of the nervous system—a knowledge which the ordinary physician rarely possesses Nevertheless, the bounds of neurology are very indistinct, and the victims of many neurological diseases require to a particularly high degree that sympathetic understanding from their medical advisers which the specialist so typically lacks The best neurologist, therefore, is probably not he who devotes his whole attention to the nervous system but he who is a general physician as well

Selection and Training of Specialists and Consultants

In recent years in Britain the typical potential specialist or consultant does some house appointments after qualification, obtains higher degrees or diplomas, becomes a registrar and, after three or more years, is appointed to hospitals with the title of consultant This process no doubt turns out men who are very knowledgeable in their subjects and (if they are surgeons) have mastered some technique But I believe it fails to give men the ability to see the problems of medicine in proper perspective It has often struck me that the average surgical registrar tends to be interested in operating, to the exclusion of all else The interest of the average medical registrar, on the other hand, is particularly aroused by the very rare and obscure case Some general physicians and surgeons may in course of time overcome the defects of their early training, but the whole manner of working of the ultraspecialists tends to distort their perspective, with the result that they may fail to inculcate the right attitude into their own registrars, whose attitude at the beginning of *their* consultant careers may in consequence be particularly distorted

The problem would, I believe, be largely solved if all clinical registrars were selected from the ranks of the general practitioners The minimum period spent in general practice should be, say, three years (It should not merely be a matter of months, for then it might easily be considered as a wasted interlude before returning to hospital and doing once more "real medicine," in the shape of inserting cardiac catheters, studying electro encephalograms, estimating 17 ketosteroids in the urine, and other similar procedures) Every medical student who intended to become a clinician would then naturally acquire the idea that the purpose of his training was to make him a competent general practitioner

Specialists recruited in this way could hardly be interested in the defects of some small region of the body to the exclusion of all else, but would also be interested in *patients* They would not be so blind to the psychiatric aspects of organic disease or the disturbing effects of psychiatric upsets on the bodily organs And they would better appreciate that the good general practitioner wishes to have advice as to how his patients can be helped, not a learned dissertation on some obscure aspect of a rare disease

The majority of general practitioners would applaud such a scheme as this and would accept more readily the opinions of consultants who had themselves been in general practice than of those who had spent their whole careers in the artificial atmosphere of a hospital If their patients were seen by a registrar instead of by the chief, they would not—as they often are now—be particularly annoyed The scheme would carry with it the further advantage of discouraging the recently qualified from hanging about teaching hospitals doing odd jobs as clinical assistants while waiting for registrarships to become vacant, and the ex registrars from acting similarly while waiting for dead men's shoes Perhaps general practice would become, not the last refuge of those who could do nothing else, but the usual goal of a high proportion of medical students

Conclusion

The main justification for specialisation among clinicians is the necessity for mastering difficult techniques The various branches of surgery are all legitimate specialties for therapeutic reasons, and ophthalmology, otorhinolaryngology, and perhaps a few others are also legitimate for diagnostic reasons The same considerations apply to anesthetics and radiotherapy But in the field of medicine as opposed to surgery, and also in the important part of surgery which precedes the actual operation, there is little to be said in favour of specialisation, and much to be said against it The modern tendency to subdivide physicians into cardiologists, gastro enterologists, phthisiologists, diabeticians, rheumatologists, kidney specialists, and the rest is regrettable Even in so far as certain medical specialties, such as pediatrics and neurology, are justifiable, those who practise them would usually be better if they were also general physicians

The value of the physician is derived far more from what may be called his general qualities than from his special knowledge A sound knowledge of the ætiology, pathology, and natural history of the commoner diseases is a necessary attribute of any competent clinician. But such qualities as good judgment, the ability to see the patient as a whole, the ability to see all aspects of a problem in the right perspective, and the ability to weigh up evidence are far more important than detailed knowledge of some rare syndrome, or even the possession of an excellent memory and a profound desire for learning Many of the eminent consultant physicians of the 19th century were said to be quite aware of their superior general qualities One gathers that they did not hesitate to reach confident conclusions about their cases, while lesser men unhesitatingly obeyed their orders The average modern physician appears more modest (perhaps because he is aware that some later investigation may disprove any confident statement on his part), and prefers to accept the view that his detailed knowledge rather than his superior mental prowess justifies his position If he is a gastro enterologist, he may refuse even to look at a patient who has cardiac symptoms, but may be resentful if a physician who is not a gastro enterologist questions his verdict on a dyspeptic subject But if a consultant physician lays no claim to infallibility in any situation and essays to do no more than give general practitioners a second *opinion* in cases where they are in difficulty, there is no implication that his mental prowess is of a different order to that of those he is advising

If these views are sound, even the general practitioner (except in so far as he may lack certain facilities) is often in as good a position as the most learned specialist to reach the right conclusions about his cases I am not concerned here with the question of whether or not the standard of general practice is in fact high But I believe that the patient with a "medical" condition is far better off under the care of a first rate general practitioner than of an indifferent specialist who is an authority on the particular condition under consideration On the other hand, no general practitioner is competent to do a difficult surgical operation

Much has been heard in recent years in Britain of the shortage of specialists As regards physicians, I do not believe that there is any real shortage The medical outpatient departments of many hospitals are no doubt overcrowded, but much of the overcrowding is due to the attendance of patients whose general practitioners desire, not a second opinion, but an investigation which they cannot get done themselves More overcrowding is due to the public's insistence on seeing a specialist, and to bad general practitioners who refer cases unnecessarily

The present difficulties should, I believe, be overcome not by multiplying specialists, but by increasing the number and improving the quality of general practitioners, by giving them the facilities which so many now lack, and by a propaganda campaign to persuade the public that there is no magic in the name specialist Top priority in the capital development schemes of the National Health Service should be given to the provision of health centres where general practitioners could have the more important investigations done For even when the present day enthusiasm for investigating is discounted to the utmost, no doctor can be efficient without the aid of certain X ray films, blood counts, urinary examinations, and a few other tests

Summary

The need for specialisation in diagnosis, treatment, and research is considered

The conclusion is reached that the main justification for specialisation among clinicians is the necessity for mastering difficult surgical techniques, and that in medicine specialisation is in general harmful. The view is advanced that registrars should be selected from the ranks of the general practitioners

I wish to thank Sir Henry Cohen for his encouragement and my father for his help in revision.

Parliament

Penicillin (Merchant Ships) Act

In the House of Lords on Feb 15 the Royal Assent was given by commission to this Act

QUESTION TIME

Hospitals and Electricity Cuts

In answer to a question Mr Alfred Robens, parliamentary secretary to the Ministry of Fuel and Power, said that the system of telephone warnings of power cuts to hospitals and other large users was being extended and experiments were being made with special short-wave radio transmitting and receiving sets There were however still formidable difficulties to be overcome

Children's Emergency Fund

In answer to a question Mr Ernest Davies, under secretary of state for foreign affairs stated that the Government were proposing to ask parliamentary authority for a further contribution to be made to the United Nations International Children's Emergency Fund of £100,000

Tuberculous Pensioners

Brigadier A H Head asked the Minister of Pensions what were the numbers of tuberculous pensioners of the 1914–19 war and the 1939–45 war, respectively, and the total numbers of those two categories who were classified as 100% disabled —Mr G A Isaacs replied The numbers are estimated to be 17,000 and 52,000 respectively, of these pensioners 3800 and 28,700 respectively are estimated to be in receipt of pension at the 100% disablement rate

100 per cent Disablement Pensions

Brigadier Head asked the Minister how many pensioners were now receiving the 100% rate, plus both the unemployability supplement and constant attendance allowance — Mr Isaacs replied 4550

Marriage Allowances of National Service Medical Officers

Dr Charles Hill asked the Minister of Defence whether he was aware that married National Service medical officers, aged 25 years or over, received a marriage allowance of 12*s* 6*d* a day, as compared with a corresponding allowance of 18*s* 6*d* a day payable to short service or permanent officers, and whether he would remove this anomaly, having regard to the fact that the upper age limit for the conscription of medical practitioners was 30 years, as against 26 years for other sections of the community —Mr Emanuel Shinwell replied The increases in marriage allowance given to regular officers in November, 1948, were intended to meet exceptional expenses which are not normally incurred by National Service officers, whether medical officers or not It is therefore, not possible to treat medical officers in this respect more favourably than other National Service officers Dr Hill Bearing in mind that the upper age for conscription for medical officers is 30 and, further, that the cost of maintaining a wife, special expenses, and other burdens is no less to a National Service officer than to a short-term officer, will the Minister reconsider the position ? Mr Shinwell We went into the matter very carefully in order to avoid all possible hardship The fact is that the liabilities of the Regular medical officer are much more severe than in the case of the National Service officer

Identification of Gas Cylinders

Dr Hill asked the Minister of Health whether he was aware of the recommendations proposed by a representative conference of the medical profession to introduce at an early date an agreed code of colour markings of gas cylinders and for the manufacture and use of a non interchangeable valve that could be attached to United States and British cylinders with the object of avoiding fatal accidents as a result of the misidentification of a cylinder prior to or during the administration of an anæsthetic, and what steps he proposed to take to provide doctors within the National Health Service with the cylinders and valves they desired to eliminate fatal accidents —Mr H. A Marquand replied I am aware of the recommendations referred to A colour code and non interchangeable valves are under consideration by the British Standards Institution and the International Organisation for Standardisation When agreement is reached urgent consideration will be given to revision of the existing British Standards

Cost of Drugs

Mr H. Hynd asked the Minister of Health what was the average cost per patient of drugs supplied direct to the patient by chemists under the National Health Act for the last 12 months for which figures are available —Mr Marquand replied The average cost (including chemists remuneration) of drugs supplied per person on prescribing doctors lists for the year ending Dec 31, 1949, was 15*s* 7½*d*

Hospital Accommodation for Chronic Sick

In answer to a question Mr Marquand stated that 7712 chronic sick persons in England and Wales were awaiting admission to hospital on Dec 31, 1949, the latest date for which complete returns were available On the same date there were in chronic sick hospitals 7575 empty beds more than half of which were unstaffed

War-time Lists in Tuberculosis Treatment

In answer to a question Mr Marquand stated the number of cases of tuberculosis awaiting admission to hospitals or sanatoria at Dec 31 last in the North west, North east, South east, and South west metropolitan areas respectively were 1566, 933 1087, and 1200

Medicine and the Law

Ministry's Liability for Hospital Staff's Negligence

As long as the authority of Hillyer *v* St Bartholomew's Hospital (decided in 1909) prevailed, it could be contended that a hospital had the duty to use care in selecting the surgeons, doctors, or nurses on its professional staff, but was not liable if the staff acted negligently in a matter of professional care or skill Lord Justice Kennedy's judgment said so, Lord Justice Farwell decided the case on narrower grounds In Gold *v* Essex County Council in 1942[1] the Court of Appeal reviewed Hillyer's case and chose to follow Lord Justice Farwell, it declared that Lord Justice Kennedy, in his remarks about nurses, went far wider than the scope of the case required, and that, as Lord Dunedin observed in Lavelle *v* Glasgow Royal Infirmary, those remarks were mere *obiter dicta*

It is now certain that the liability of a hospital is much more extensive than was supposed in Hillyer's case in 1909 This was made clear afresh by the Court of Appeal in Cassidy *v* Ministry of Health on Feb 15 Mr Cassidy went into a Liverpool hospital with a condition of his left hand which was diagnosed as Dupuytren's contracture An operation was carried out, the treatment involved keeping the hand and lower arm rigid in a splint for several days When the hand was released after 14 days, two fingers (those operated upon) were completely stiff and two others were affected, the left hand had become useless He sued Liverpool Corporation, which then owned and controlled the hospital, later, when the National Health Service was initiated, the Ministry of Health was substituted as defendant, the Ministry brought in a Canadian doctor, at the time of the operation a whole time assistant medical officer of the hospital, as third party The doctor's evidence was taken on commission in Vancouver

At the trial Mr Justice Streatfield, without deciding whether the doctor was a servant or agent of the Ministry or whether the Ministry would be liable for his negligence in that capacity, held that no negligence had been established against the doctor or any other member of the hospital staff The Court of Appeal says this was wrong it seemed to be a case of *res ipsa loquitur*—the thing spoke for itself—and a jury could have found negligence on the facts as stated But, if so, was the Ministry liable? The doctor was employed, like the nurses, as part of the permanent staff of the hospital If, in the phrase used by Lord Greene in Gold's case, a patient knocked on the door of a hospital, he would expect to find inside medical and surgical treatment and nursing, if the treatment or the nursing were negligent, the hospital must be liable, whether the fault was that of a nurse or of the permanent medical staff Lord Justice Denning, whose powerful argument at the bar in Gold's case will be remembered, said that a hospital endeavours to cure by means of the staff which it employs, it has no ears of its own with which to listen through the stethoscope, and no hands to hold the knife If its staff is negligent, it is just as much liable for the negligence as is anyone else who employs others to do his work for him If a patient himself selects and employs doctor or surgeon (as in Hillyer's case), the hospital is not liable, but, if doctor or surgeon, whether a consultant or not, is employed and paid by the hospital and not by the patient, the hospital is liable for his negligence in treating the patient The Ministry of Health, it seems, can now sue the Canadian doctor, if it so desires

In England Now

A Running Commentary by Peripatetic Correspondents

We cannot eat but little meat,
The ration is not big
We try no end to make a friend
Of one who keeps a pig
The butchers' shops contain no chops,
Nor luscious offals hold
I ask you, Webb, at this low ebb
—If I may make so bold

Back and sides go where, go where?
For export? Are they sold
For bully? God knows who consumes the stuff
—Pass me the prunes and mould

We have no roast to play the host
—We dare not light the fire—
But ancient ewe we have in lieu
Such ewe we not desire
We have no stint of spuds or mint
But no allaying lamb,
And, as I live, what wouldn't we give
For a jolly good chunk of ham?

Back and sides go where, go where?
For export? Are they sold
For bully? God knows who consumes the stuff
—Pass me the prunes and mould

* * *

It would be nice if the committee now considering general practice could find some way of rewarding practitioners according to the responsibilities they really undertake rather than by mere head counting A little while ago I was called in consultation by an elderly doctor practising in an unprosperous suburb "I have never seen a case like this before," he told me, "but I have read of them I think it is a spontaneous pneumothorax. We were not taught about that in my student days." At the patient's house we found a young man who gave us the characteristic history of sudden pain in the chest and shortness of breath, and he had the textbook signs. After giving him a few words of reassurance and arranging for a chest X ray later, we left

The point of the story is that there was no suggestion that the patient's proper place was in hospital—and this in an area where doctors send people to the outpatient department to have their urine tested One does not want to tempt any man to assume responsibilities beyond his skill, but surely my elderly friend deserves a larger reward than those who cannot treat a straightforward pneumonia without the aid of the Emergency Bed Service?

* * *

Doctor's letter to his executive council

"This is not a complaint but a record of Mr T, who sent for me to visit him at home, but who happened to be arriving on his bicycle as I arrived to see him He was informed that if he was fit to ride a bicycle on a frosty day he ipso facto is fit to attend this surgery, and I did not go upstairs to see him Please do not trouble to reply as I consider this sort of happening to be part of our daily relationship with the public as a whole"

Medical benefit committee's comment

The Service regulations make no provision for the investigation of a complaint by a practitioner against a patient

And that's that

* * *

When my wife drew attention to his little pigs in our garden, Mr Larks did not, as expected, engage to keep these animals on his own side of our fence All he said was "Wonderful what they do in the time!"

One's wife of course is prejudiced, living on the spot, and I like to take a broader view In the past few thousand years, I said to myself, this situation must have arisen before There must be a Precedent, and wherever freeborn Englishmen gather they will know about pigs invading gardens Encountering some free-born Englishmen in the train, I was glad to find that Mr Larks hadn't a leg to stand on. Rabbits—yes Rabbits are creatures of the wild, and if I want to keep them out I must make my fence rabbit-proof But pigs—no The pigs of Sussex are now definitely domesticated, and their owners are therefore bound to see that they don t ravage neighbouring property

Very true said I But just for confirmation I raised the question again in the help-yourself department of my club—which not only contains freeborn Englishmen but is practically the remains of the old Saxon Witanagemot After tactfully offering to advise a solicitor on how to get his ward trained as a hospital dietitian, I felt I could decently broach my pigs What, then, was my horror—and that of many clubmen present—to hear him say at once that anyone who wants to keep an animal (or, no doubt, several animals actually in this one litter there are 11, and more are promised) off his property must erect and maintain a fence that will keep it (them) out' But suppose Mr Larks bred vipers, I cried must I then reinforce my fence with zinc gauze ? Vipers are different, said the lawyer , they are Dangerous Animals If my present fence does not keep out small pigs (and it certainly doesn t) and if such pigs effect an entry (as they certainly do) I may not even eat them . all I may do is impound them and ask the owner to take them away, or see that they are conducted back to the boundary without unnecessary use of force (Actually I have already entrusted this latter duty to our dear dog)

All this information sounds simple in the clear way I've set it down , but it was complicated by the interjections of a kind but slightly deaf man a little way up the table who thought I was seeking help over the old problem of keeping cats from asphyxiating my baby He suggested a net over the pram He also thought that dogs should not be kept for pleasure, and that the care so often lavished on pet animals should be devoted to our own species

I should be more upset about all this but for a very wise remark made by one of the most venerated members of the Witan He recommended me to revenge myself on Mr Larks by keeping on my premises, not necessarily under complete control, a number of animals of a kind more subtle and more destructive even than pigs It was then I remembered that my wife and I did in fact choose our present home largely because we thought it would be nice for Andrew, Duncan, Colin, and Robin to see a good deal of the farm

* * *

During the Christmas holidays the family took me for my annual visit to the pictures There was an excellent programme, but what interested me particularly was a short film produced under the auspices of the New Zealand government, which vividly portrays the voyage made four times a year by an auxiliary ketch, the *New Golden Hind*, as a relief ship to some of the distant Pacific islands administered by the Dominion I have been reading, more or less in their original form, Captain Cook's diaries of his voyages among these very islands Besides being fascinating adventure stories these diaries contain much medical information For Cook was not only a superb seaman but also remarkably well versed in preventive medicine In applying the medical knowledge of the time he was ably supported by the surgeons who sailed with him, and their joint efforts were a major factor in the success of the expeditions The film shows what hazards this great navigator had to face in the Pacific and his descriptions apply equally well today If he had come with me to the cinema though he would have been astonished at the changed conditions of life on the islands and dumbfounded at the medical and dental services supplied for the inhabitants by the New Zealand government. If all the Europeans who visited the Pacific in early days had been of Cook s calibre the islanders would have escaped a great deal of disease and ill-treatment, but it is comforting to know that so much is being done to atone for the past evils

Aphorism of the Week

Lay the ghost of your buried mistake next time

Letters to the Editor

DIAMINODIPHENYLSULPHONE

SIR,—I am sorry that my old friend Dr R G Cochrane (in your issue of Feb 3) reported so much difficulty with the treatment of leprosy with D.A.D P S in India This treatment might well claim him as its father, for he was the first worker to use it,[1] unfortunately in doses too high to avoid toxicity Even now, with a much reduced dosage, he finds his child troublesome, and would apparently rather like to disown it There are, however, plenty of other workers who are keen to adopt it, some of them in India [2–5] In the Nigeria Leprosy Service it is the standard treatment, and now, in February, 1951, 17,000 cases are receiving this treatment Several other published reports [6–15] and several personal communications are favourable , and, in fact, of all the many workers who have now tried it, only one group—the group in India headed by Cochrane—has reported rather adversely on it and prefers to inject ' Sulphetrone ' As already stated, other workers in India have reported favourably on D A.D.P.S

There is general agreement that the maximum well-tolerated dose is 200–300 mg a day [6–15] Indians apparently tolerate rather less, 100–200 mg a day [2–5] The minimum active dose is very low , 50 mg a day is effective [3 16] I have found even 30 mg a day to exert a definite action As I have indicated,[9 10] the optimum dose is not yet fixed Our standard dose for mass treatment in Nigeria is now 800 mg a week (400 mg twice a week) very slowly attained, which is the same as that now suggested as the maximum by Cochrane himself There seems little difference of opinion here

But there is one important point on which I do differ from Cochrane He states that the main objection to sulphetrone treatment is its high cost which can be remedied by using injections of much smaller doses than those used orally This matter was fairly fully discussed by me in your pages [9] There is now very strong evidence to support the view then expressed, that disubstituted sulphones, such as sulphetrone, act only by being hydrolysed to D.A.D P S , that when they are given orally this hydrolysis occurs mainly in the stomach, and that the injection of drugs such as sulphetrone prevents this hydrolysis All the evidence on this point cannot be quoted here, but the recent papers of American,[17 18] French,[15 19] and British [20] workers may be studied on this point , all these papers report studies, in vitro and in animals, indicating that without hydrolysis to D.A.D.P S , sulphetrone is not active In a paper now in preparation I am reporting similar results in vitro and in man Opinion on these matters now seems unanimous

It now appears that injections of sulphetrone probably act by means of DADPS, some being present as an impurity in the sulphetrone, some being produced by hydrolysis during sterilisation, and perhaps a little being produced by hydrolysis in the body

The main objection to the use of sulphetrone, particularly by injection, is not its high cost, the main objection is that it is irrational, and not in accord with the steadily increasing knowledge of the mode of action of sulphones It is such a roundabout and inefficient way of securing the action of DADPS in the body

Cochrane hesitates to accept Muir's statement about the effectiveness of DADPS in low doses (300 mg a week), but Muir has been treating some hundreds of cases, moreover Molesworth has been using doses not very much higher for at least two and a half years, and his cases must now number well over a thousand, he reports excellent results [8] In experiments carried out here, we find that the DADPS blood-level on 300 mg a week is considerably higher than on the 6 g a week of injected sulphetrone that Cochrane recommends

By being the first leprosy worker to draw attention to the possible usefulness of DADPS in the treatment of leprosy, Cochrane rendered a great service We hope that he will soon be able to agree with the large and increasing number of workers who find that this treatment, which he did so much to initiate, is safe and widely applicable, especially if modified to meet local conditions

Finally, while all will agree with Cochrane that sulphone treatment does not present the solution of the leprosy problem, properly used it is being found a great help to all aspects of anti leprosy work, even to attempts to segregate infectious cases In Nigeria, the prospect of a shorter period of segregation, and the painlessness and greater efficacy of the treatment, as compared with the past, are encouraging more patients to come for segregation and treatment, and to come at an earlier stage of the disease

We are all trying to find a more rapidly effective remedy than sulphones, or an agent to augment and speed up the action of sulphones, and the thiosemicarbazones are giving promising results In the meantime it is not by failing to acknowledge the great advances already made that we shall attract the badly needed medical staff to the leprosy services (the Nigeria Leprosy Service has less than one doctor to every 2000 patients !) or the patients to make full and proper use of those services

DEFINITION OF TUBERCULOSIS

SIR,—Dr Barran (Feb 10) has rightly called attention to the widely differing criteria used in the notification of tuberculosis It will be generally agreed that it is undesirable that all persons should be notified who have suffered a tuberculous infection, just as it would be equally useless to notify only those who are infectious However, some degree of uniformity is desirable The following criteria, as used in the Ipswich and East Suffolk Chest Service, are put forward as practical

(*a*) All patients from whom tubercle bacilli are isolated

(*b*) All patients suffering from tuberculous disease who are in need of treatment

By treatment is meant any change in the working or home life necessary to encourage healing of the disease, as well as the more definite forms of treatment, such as bed rest and "relaxation" therapy This would include Dr Barran's "minimal tuberculous lesion of the lung found to be healing without active treatment", for surely such a patient would be advised to rest in his off duty time and even perhaps to take a day in bed at the weekend It would also include active primary tuberculous infections of childhood where it was necessary to modify school life by recommending an open air school, or a regular rest period, as well as the more specific forms of treatment

In all these cases it may be necessary at some time to issue certificates *indicating that a patient is suffering* from tuberculosis

I would add that I think it essential to examine the household contacts of all patients diagnosed as having suffered or as suffering from tuberculous disease, even if they have only a calcified primary lesion (this could be done by mobile mass radiography) Notification of healed cases is not necessary, since after explanation most patients and their relatives readily agree to examination

ÆTIOLOGY OF CHRONIC GASTRIC ULCER

SIR,—Mr Doran's paper of Jan 27 requires brief comment Mr Doran claims to show, by injection techniques, that the mucosa of the lesser curve has a "lower vascular density" than has the rest of the stomach mucous membrane This would be an attractive finding, in view of the present re emphasis on vascular factors as a cause of peptic ulceration, but it is unfortunately not correct Injection techniques require careful control before quantitative differences can be claimed between different preparations Such factors as the time interval between removal of the tissue and its *injection*, the particle size of the silver iodide preparation, the pH of the injection mass, and, above all, the pressure at which injection is carried out are factors which can profoundly modify the degree of filling of the vessels of the injected tissue

Mr Doran uses for injection a syringe and fine hypodermic needle, continuing the injection until a "slight resistance" is felt The human thumb is a fallible organ as a scientific instrument If the gastro epiploic arterial chain of a resected stomach is injected with 10% colloidal silver iodide, using a 20 ml 'Record' syringe and a hypodermic needle no 17 (0 5 mm diameter, standard wire gauge [S W G] 25), the pressure within the chain is

	mm Hg
Moderate pressure, one thumb	20
Maximum pressure, one thumb	52
Maximum pressure, both thumbs	78

Using a "fine" hypodermic needle no 20 (0 45 mm diameter, S W G 26), the figures are

	mm Hg
Moderate pressure, one thumb	16
Maximum pressure, one thumb	45
Maximum pressure, both thumbs	54

In each case there is a wide variation in pressure at which the injection mass may be introduced, and even the maximum pressure of 78 mm Hg using a hypodermic needle no 17 and the full strength of two hands is inadequate to fill completely the vessels of the stomach, as experience shows

Mr Doran is comparing specimens of stomach wall in which the vessels are filled with varying degrees of success Precise technique shows that the size, arrangement, and density of vessels within the mucosa is the same in the lesser curve region as in the anterior and posterior walls of the stomach, and the number of mucosal arteries supplying each square centimetre of mucosa is the same in the different parts There are differences in the vascular supply to the lesser curve, but these lie within the submucous layer and outside the muscle coat, and do not result in any difference in the vascular pattern of the mucous membrane

So far as we know, the significance of arteriovenous shunts in the stomach wall in the causation of peptic ulceration has only been mentioned by Dr W C. Alvarez, of the Mayo Clinic, in a discursive leading article, and there is much that can be argued against this view eriovenous anastomoses are shown most accurately the stomach wall by micro dissection They are g direct channels, up to 140 μ in diameter in life, ining from mucosal artery to vein, and it is usually sible to find one arising from each mucosal artery in submucosa Examples are reproduced in the *Journal Anatomy*[1] They are present equally in the anterior d posterior walls and in the lesser curve regions It necessary to understand the architecture of the vessels, t the problem remains one of blood flow under different nditions and it is no doubt because we know so little out this that speculation, both negative and positive, s its opportunity

NORADRENALINE AND THE SUPRARENAL MEDULLA

SIR,—Holtz and Schümann[2] reported that noradrenane is present with adrenaline in the normal suprarenal edulla of man, but it is not accurately known what roportion of each amine is present We have investigated y biological assay and chromatographic methods the atechol content of extracts of suprarenal glands obtained ost mortem

In 17 adult cases (ages 45–79) secured 2–49 hours fter death, noradrenaline was present to the extent of bout 14% of the total amines (mean value of nor-drenaline = 29 μg per g fresh tissue) In 9 children nder 1 year, however, the mean value of noradrenaline vas 65 μg per g fresh tissue, representing 90% of the otal amines present These latter samples were secured 4–22 hours after death

The significance of this finding is not yet clear

THE INVESTIGATION OF SUGAR TOLERANCE

SIR,—Dr Friend's article of Jan 27 should not pass unchallenged as it denies any value of a full blood sugar curve in the following words "Complete standard tolerance tests cannot be justified, since the only information obtained from the five blood and three urine examinations of the test can be found equally well by estimation of a single 2 hour blood sugar level"

True, one admits the great importance of a return to normal in 2 hours, but mistakes will be made from this figure alone and much information omitted which can be obtained from a full blood sugar curve For example

1 No explanation of glycosuria—and it is to explain symptomless glycosuria that blood sugar investigations are undertaken—is given by the 2 hour figure Dr Friend does not mention glycosuria in his suggested test and hence would have no clear evidence on renal glycosuria or oxyhyperglycæmia

2 Without the fasting level, starvation curves (not uncommon apart from absolute starvation) would be labelled as diabetic from the raised 2 hour figure alone

3 The same would apply to thyrotoxic and certain toxæmic disturbances of the blood sugar curve

4 I am certain that I would often be misled in life assurande and other work by one 2 hour figure instead of a full curve which shows the total response to glucose tolerance by five or six blood sugar estimations and simultaneous urine tests

In any full assessment, knowledge of general health factors not mentioned in Dr Friend's analysis, is also most important

London W 1

R D LAWRENCE

VACCINATION AGAINST SMALLPOX

SIR,—Allow me to reply to letters arising from my article of Jan 13

Dr Dixon (Jan 20) says "Dr Millard's main argument is that mild cases of variola major only occur in the vaccinated In my opinion this is fundamentally wrong" Dr Dixon has not got me correctly I said of the unvaccinated "The mild and trifling cases [I was referring to the ultra mild cases which are so easily missed] very rarely occur when we are dealing with true major smallpox but only when we have to do with a mild strain of the disease, and, when this is so, the mildness tends to breed true"

Dr Dixon quotes some figures from his own experience of smallpox in Tripolitania, where out of 300 unvaccinated cases 105 were classed as types 6 and 7 (discrete and mild) Such cases would be very different from the trivial cases I was considering, which are so mild and modified that they may deceive even experts Moreover, as he does not mention the number of fatal cases we have no means of knowing whether they could rightly be regarded as true major smallpox such as occurs in India I doubt very much if they were

As regards India, Dr Dixon takes exception to my suggestion that it might be worth while trying the experiment of substituting inoculation with variola minor for vaccination He thinks it would "confuse patient and medical profession alike" This surely is hardly an insuperable objection! He further writes "It is very doubtful if 5% of India's total population are immune at any one time One would not expect this to have any appreciable effect on incidence, but the fault is not with vaccination" I cannot agree that vaccination is not to blame It is because the protection conferred by vaccination is so short lived in the face of really virulent smallpox that so small a proportion of the population is efficiently protected Let there be no mistake vaccination has been "pushed" in India for very many years as far as is practicable, so what more does Dr Dixon suggest? There has been more vaccination in India in proportion to population, than there has been in this country, certainly during the past half century The latest figures I have by me are for the year 1936 taken from the Bengal health report for that year On p 40 I read 'Smallpox 46,267 deaths were due to smallpox in the province yielding a death rate of 9 per 1,000 Smallpox accounted for 3 8% of the total provincial mortality" The population of Bengal is given as 51,000 000, which is very little more than that of the United Kingdom plus Eire If we had 46,000 deaths from smallpox in this country in one year, or only a fraction of that number, we should certainly regard our preventive measures as a ghastly failure And here are the vaccination figures (p 116)

Vaccination in Bengal 1935–36

Total number of persons vaccinated	9 106 830
Total number of vaccinations performed	9 114 092
(*a*) Primary	2 907 210
Successful	2 557 500
(*b*) Revaccinations	6 206 882
Successful	2 216 873
Ratio of successful vaccinations per 1000 population	95 3
Total number of births	1 673 206

I think that these figures may surprise some people, they certainly surprised me

I think we may assume that the reason why preventive measures have failed so lamentably in India are (1) the obvious impracticability of carrying out those measures which have been so signally successful in this country (hospital isolation and tracing and surveillance of contacts), (2) the extreme virulence of the disease, against which only recent vaccination is effective As I mentioned in my paper, British troops in India had to be revaccinated every two years It would obviously be quite impossible in India, or indeed in any country, to apply this to the general population

So far as we know, the significance of arteriovenous shunts in the stomach wall in the causation of peptic ulceration has only been mentioned by Dr W C Alvarez, of the Mayo Clinic, in a discursive leading article, and there is much that can be argued against this view

A VISIT TO INDIA

SIR,—Last October and November I was privileged to take a party of medical practitioners from this country for a goodwill tour of India The trip, I am glad to say, was most successful, and the welcome and hospitality extended to us by my countrymen in India were so unstinting and sincere that I am now making arrangements to repeat the tour over a period of six weeks during October and November of this year

The party will travel by air between London and Bombay, and all journeys during our stay in India will be made either by air or by rail Our itinerary will include visits to places of historical and archæological interest as well as to universities hospitals, and cultural centres in Bombay, Mysore, Bangalore Hyderabad, Madras, Delhi, Agra, Kashmir, Calcutta, and Darjeeling The total cost will be approximately £250 per person

My primary objective in organising the tour is to stimulate full comprehension of India's vast potentialities in those persons who, through active work in their profession, are most favourably placed to strengthen the ties of friendship between Great Britain and India Inquiries *from doctors* wishing *to* join the *party* should reach me before March 31

METHONIUM COMPOUNDS IN HYPERTENSION

SIR,—Our cases of hypertension treated with methonium compounds now number 50, and many of them have been followed as outpatients for almost six months Most of these were cases of essential hypertension with severe headache or left ventricular failure, 2 had had bilateral sympathectomy without benefit, and 1 had malignant hypertension

Our method of administering the drug was to give 25 mg by injection intramuscularly and observe the blood pressure at fifteen minute intervals for the next two hours If this initial dose was unsatisfactory it was increased by 10 mg or more and the procedure was repeated until we obtained what we felt was a satisfactory fall in blood pressure The drug was then given by injection six-hourly, and as tolerance increased the intervals were reduced until in some cases the patients were having as much as 100 mg three hourly After seven to fourteen days on injection the patient was transferred to the drug by mouth We considered that a suitable dose to commence with would be 250 mg by mouth at the same time interval as every 50 mg was given by injection In some cases the patients had as much as 7–8 g daily by mouth

Before any patient was started on methonium treatment he was given a fortnight's rest in bed, and his blood pressure was taken at frequent intervals during the day When the patient was put on the drug his blood-pressure was taken even more frequently All the injections were given with the patient sitting up, and a few patients were ambulatory After four weeks in hospital all the patients were up and about They were then seen as outpatients fortnightly or more often

Since finding a case of bromide poisoning about five months ago we have estimated the serum bromide level *fortnightly on every patient receiving* hexamethonium bromide We found that every patient had a reasonably high serum bromide level, and owing to the slow excretion of bromide these serum bromide levels tended to increase at about the same rate, irrespective of the dose of the drug, or at least provided the dose was between certain fairly wide limits We have recently had a second case of bromide intoxication in a patient whose blood pressure did not fall in spite of the fact that he was receiving at one time 12 g of hexamethonium bromide by mouth

Our results, which we hope to publish in detail shortly, have been unsatisfactory Unquestionably injections of the drug, and in some few cases oral administration, will produce an acute fall in blood pressure Sometimes, however, in spite of large doses of the drug, even this acute fall did *not* occur In all cases except 1, oral administration of the drug failed to keep the blood-pressure down, and every patient so far seen at outpatients has had a blood pressure at the same level as it was before treatment was commenced, though many patients admitted to feeling much better The initial fall in blood pressure obtained with methonium compounds is often, in our experience, no greater than that produced in many patients by rest in bed

We agree with the writers who have suggested that at present these compounds should only be used under hospital observation The production of a drug which has a longer action than the hexamethonium compound and which does not contain the bromide radicle, or alternatively is effective in much smaller doses, would be the ideal to aim at

Oldchurch Hospital

SIR,—After Kay and Smith [1] observed that the potency of the halide salts of hexamethonium given orally, expressed in terms of the cation, was highest for the iodide and lowest for the chloride, with the bromide intermediate, clinical studies of this drug have been made mostly with the bromide or iodide It seems improbable, however, that the halide anion of such a salt, which must be completely dissociated in solution, *can exert any significant effect on the activity* of the hexamethonium cation, or even on its absorption In view of the possibilities of bromism[2] and of iodism from the use of the bromide or iodide, we have been prompted to test the purity of some of the available preparations in order to determine whether the reputed inefficacy of the chloride was associated with any impurity, and to verify whether, with pure salts, the biological activity of the cation did indeed vary with the different halide ions We have determined the halide content of samples of hexamethonium salts, and have assayed biological activity, using the antagonism of hexamethonium to the action of acetylcholine on the frog's rectus abdominis (limits of error 7–10%, $P = 0\ 05$) The results were as follows

Hexamethonium salt	*Biological activity*	*Halide content (% theoretical)*
1 Iodide	93	94
2 Iodide	100	99
3 Iodide	100	100
4 Bromide	90	94
5 Bromide	100	99
6 Chloride	80	84
7 Chloride	97	99

Biological potency is given (in terms of the cation) as percentage of that of the pure iodide (Salts 2 and 3)

It will be seen that biologically several of the salts were below theoretical potency, and that in each case there was evidence of impurity One particular cause of apparent inefficacy of the chloride came to our attention We obtained a sample of chloride which had been made up as a powder in a waxed paper, in which it had remained for some months On opening the paper no powder could be seen, but simple extraction of the paper with saline, followed by biological assay, produced 91% of the quantity of hexamethonium stated to be within the paper The chloride, therefore, is sufficiently hygroscopic to take up so much water vapour that it can go into solution and impregnate the wrapping paper

We believe, therefore, that the results of Kay and Smith may have been due to a failure to give the full dose intended, because of some impurity in the chloride

[1] Kay A W Smith A N *Brit med J* 1950 ii 807
[2] Rosenheim M L *Lancet* Feb 10 1951 p 347 Holt M. C Litchfield J W *Ibid*

It is here that inoculation with variola minor might well have a great advantage over vaccination The resulting protection against variola major would, I believe, be at least as great as that conferred by vaccination, indeed it might be much greater Furthermore, variola minor being highly infectious, a baby who was inoculated would spread the infection to other members of the family and to neighbouring families who had never been protected or whose protection had lapsed There would indeed be no limit to the effect And it should be remembered that clinically variola minor is little, if any, more serious than vaccination I speak here from my personal experience of the Gloucester epidemic of 1923 (over 1000 cases with practically no fatality)

Dr Watts (Feb 3) makes the surprising assertion that no practical alternative to vaccination has been put forward I would ask him what he supposes has enabled this country to control smallpox so successfully during the past half century He can hardly contend that it is vaccination of the general population, for this has been steadily and rapidly declining, and now that compulsory infant vaccination has been abandoned it is likely to decline still further No, the real cause of our success has been prompt isolation plus the searching out and close surveillance of contacts, and the only thing which defeats these measures is the missed case, which, as I tried to show in my paper, vaccination of the general population tends to encourage

May I remind Dr Watts that during the last century before efficient modern measures were introduced vaccination of the general population, though carried out far more thoroughly than during the present century, entirely failed to protect this country from really severe epidemics of smallpox accompanied by a heavy death roll, as reference to the Registrar General's reports will show

Dr Woolman (Feb 10) thinks that I invalidate my thesis by saying that I am in favour of all who visit the East being protected by recent vaccination I am also in favour of such people being inoculated against typhoid, but I do not think it necessary that everyone in this country should be similarly inoculated

Leicester C Killick Millard

SECRECY OF SERVICE MEDICAL REPORTS

Sir,—Your timely article of Feb 10 (p 343) calls attention to an increasingly unsatisfactory position

The reference to the inquest on the soldier who dropped dead during a course at the Guards' depot, Caterham, may, I think give the impression that privilege was claimed for the evidence of the Army doctor for whose attendance, among other things, the inquest was adjourned, this is not so, nor would it be possible to claim privilege in this way The Army doctor was summoned to the inquest from Germany He duly attended, and gave most comprehensive evidence of his previous examinations

Privilege was in fact claimed, supported by a certificate signed by the Secretary of State for War, for the production of the medical history sheet of the deceased soldier Counsel who appeared on behalf of the War Office *at the inquest stated that privilege was always* claimed for documents of this kind, and the fact that privilege is automatically claimed in every case irrespective of the particular facts, seems to be one of the more objectionable features of this practice Lord Simon's judgment in Duncan *v* Cammell Laird makes it clear that the refusal to produce must not be arbitrary, but must be on the grounds of injury to national defence or to diplomatic relations, or because secrecy is necessary for the proper functioning of the public service

Can it really be said that the production of a medical history sheet to a soldier (or to his relatives, when he is dead) falls within any of these classes of cases? Unfortunately the decided cases make it clear that the certificate of the responsible Minister is conclusive, and that, whatever view may be taken of the real reason for the claim of privilege, no court may go behind the certificate and inquire into the Minister's reasons

Coroner's Office, East Horsley Cyril Baron

NURSING INFECTIOUS DISEASES

Sir,—The letters of Dr Stanley Banks (Feb 3) and Prof A V Neale (Feb 17) raise many problems, not least that a general trained nurse can admit "that she has never had any practice in handling a baby, or in the principles of infant feeding"

Candidates who enter for the final general examination of the General Nursing Council for England and Wales must have had experience—not only lectures—in medical and surgical nursing, in gynæcological nursing, and in the nursing of sick children The head of the training school, usually the matron, must send a signed certificate to this effect before the candidate is accepted

Members of former councils, myself included, have often proposed that general training schools should be asked to give some details of the experience candidates have had, including experience in the nursing of sick *infants and children, and the real solution to the present lack in training is for the General Nursing Council to* bring this measure into effect With good will and good administration it could be achieved almost overnight It may mean that some of our large and well known training schools will have to second their nurses for specialised experience in this field, but the ultimate benefit would far outweigh any temporary inconvenience

London W 8 Evelyn C Pearce

SURGICAL RELIEF OF MYOCARDIAL ISCHÆMIA

Sir,—In his intriguing paper last week Mr Mason expresses his belief that treatment of angina (and, incidentally, of heart failure) by reduction of metabolic activity has now been discarded He also considers that *this treatment condemns the patient to* "a reduced level of existence"

Reduction of basal metabolism in cardiac disability is nowadays carried out by thiouracil medication, not by thyroidectomy, and it is certainly not discarded I know that at least one of the leading cardiologists of this country practises the method widely I have used it in a small series of cases selected by the crippling nature of their condition, and by the failure of all other treatment to enable the patient to lead a working, or at least an ambulant, life, or to maintain life at all in the face of advancing and intractable congestive failure *Of* 12 such patients, 1 died of (his second) coronary *thrombosis* after three years of freedom from angina *The other* 11 have continued the active life they were on the point of giving up, or have resumed activities previously beyond their scope In each case the *maintenance* treatment was, either purposely or accidentally, reduced below the required level at one time or another without the patient's knowledge The relapse that follows within one or two weeks, and the rapid restoration upon resump*tion of adequate treatment*, are a dramatic therapeutic test One of my patients, a man with a rheumatic aortic stenosis, went into failure in the autumn of 1946, became bedridden within a few months with massive œdema, anasarca, and a right sided pleural effusion (*tapped*, $1^1/_2$ pints) Under thiouracil, instituted in the nick of time, he lost all his accumulated fluid and *has not again* required digitalis or mersalyl Like all these patients, he is maintained just *above* myxœdema level, and, so far from living "on a reduced level," he has in *the meantime* become my very efficient secretary

It is here that inoculation with variola minor might well have a great advantage over vaccination The resulting protection against variola major would, I believe, be at least as great as that conferred by vaccination, indeed it might be much greater Furthermore, variola minor being highly infectious, a baby who was inoculated would spread the infection to other members of the family and to neighbouring families who had never been protected or whose protection had lapsed There would indeed be no limit to the effect And it should be remembered that clinically variola minor is little, if any, more serious than vaccination I speak here from my personal experience of the Gloucester epidemic of 1923 (over 1000 cases with practically no fatality)

Dr Watts (Feb 3) makes the surprising assertion that no practical alternative to vaccination has been put forward I would ask him what he supposes has enabled this country to control smallpox so successfully during the past half century He can hardly contend that it is vaccination of the general population, for this has been steadily and rapidly declining, and now that compulsory infant vaccination has been abandoned it is likely to decline still further No, the real cause of our success has been prompt isolation plus the searching out and close surveillance of contacts, and the only thing which defeats these measures is the missed case, which, as I tried to show in my paper, vaccination of the general population tends to encourage

May I remind Dr Watts that during the last century before efficient modern measures were introduced vaccination of the general population, though carried out far more thoroughly than during the present century, entirely failed to protect this country from really severe epidemics of smallpox accompanied by a heavy death roll, as reference to the Registrar General's reports will show

Dr Woolman (Feb 10) thinks that I invalidate my thesis by saying that I am in favour of all who visit the East being protected by recent vaccination I am also in favour of such people being inoculated against typhoid, but I do not think it necessary that everyone in this country should be similarly inoculated

Leicester C Killick Millard

SECRECY OF SERVICE MEDICAL REPORTS

Sir,—Your timely article of Feb 10 (p 343) calls attention to an increasingly unsatisfactory position

The reference to the inquest on the soldier who dropped dead during a course at the Guards' depot, Caterham, may, I think, give the impression that privilege was claimed for the evidence of the Army doctor for whose attendance, among other things, the inquest was adjourned, this is not so, nor would it be possible to claim privilege in this way The Army doctor was summoned to the inquest from Germany He duly attended, and gave most comprehensive evidence of his previous examinations

Privilege was in fact claimed, supported by a certificate signed by the Secretary of State for War, for the production of the medical history sheet of the deceased soldier Counsel who appeared on behalf of the War Office at the inquest stated that privilege was *always* claimed for documents of this kind, and the fact that privilege is automatically claimed in every case irrespective of the particular facts, seems to be one of the more objectionable features of this practice Lord Simon's judgment in Duncan *v* Cammell Laird makes it clear that the refusal to produce must not be arbitrary, but must be on the grounds of injury to national defence or to diplomatic relations, or because secrecy is necessary for the proper functioning of the public service

Can it really be said that the production of a medical history sheet to a soldier (or to his relatives, when he is dead) falls within any of these classes of cases? Unfortunately the decided cases make it clear that the certificate of the responsible Minister is conclusive, and that, whatever view may be taken of the real reason for the claim of privilege, no court may go behind the certificate and inquire into the Minister's reasons

Coroner's Office, East Horsley Cyril Baron

NURSING INFECTIOUS DISEASES

Sir,—The letters of Dr Stanley Banks (Feb 3) and Prof A V Neale (Feb 17) raise many problems, not least that a general trained nurse can admit "that she has never had any practice in handling a baby, or in the principles of infant feeding"

Candidates who enter for the final general examination of the General Nursing Council for England and Wales must have had experience—not only lectures—in medical and surgical nursing, in gynæcological nursing, and in the nursing of sick children The head of the training school usually the matron, must send a signed certificate to this effect before the candidate is accepted

Members of former councils, myself included, have often proposed that general training schools should be asked to give some details of the experience candidates have had, including experience in the nursing of sick infants and children and the real solution to the present lack in training is for the General Nursing Council to bring this measure into effect With good will and good administration it could be achieved almost overnight. It may mean that some of our large and well known training schools will have to second their nurses for specialised experience in this field, but the ultimate benefit would far outweigh any temporary inconvenience

London W 8 Evelyn C Pearce

SURGICAL RELIEF OF MYOCARDIAL ISCHÆMIA

Sir,—In his intriguing paper last week Mr Mason expresses his belief that treatment of angina (and, incidentally, of heart failure) by reduction of metabolic activity has now been discarded He also considers that this treatment condemns the patient to "a reduced level of existence"

Reduction of basal metabolism in cardiac disability is nowadays carried out by thiouracil medication, not by thyroidectomy, and it is certainly not discarded I know that at least one of the leading cardiologists of this country practises the method widely I have used it in a small series of cases selected by the crippling nature of their condition, and by the failure of all other treatment to enable the patient to lead a working, or at least an ambulant, life, or to maintain life at all in the face of advancing and intractable congestive failure Of 12 such patients, 1 died of (his second) coronary thrombosis after three years of freedom from angina The other 11 have continued the active life they were on the point of giving up, or have resumed activities previously beyond their scope In each case the maintenance treatment was, either purposely or accidentally, reduced below the required level at one time or another without the patient's knowledge The relapse that follows within one or two weeks, and the rapid restoration upon resumption of adequate treatment, are a dramatic therapeutic test One of my patients, a man with a rheumatic aortic stenosis, went into failure in the autumn of 1946, became bedridden within a few months with massive œdema, anasarca, and a right sided pleural effusion (tapped, $1^1/_2$ pints) Under thiouracil, instituted in the nick of time, he lost all his accumulated fluid and has not again required digitalis or mersalyl Like all these patients, he is maintained just *above* myxœdema level, and, so far from living "on a reduced level," he has in the meantime become my very efficient secretary

London W 1 G Schoenewald

A VISIT TO INDIA

SIR,—Last October and November I was privileged to take a party of medical practitioners from this country for a goodwill tour of India. The trip, I am glad to say, was most successful, and the welcome and hospitality extended to us by my countrymen in India were so unstinting and sincere that I am now making arrangements to repeat the tour over a period of six weeks during October and November of this year.

The party will travel by air between London and Bombay and all journeys during our stay in India will be made either by air or by rail. Our itinerary will include visits to places of historical and archæological interest, as well as to universities, hospitals, and cultural centres in Bombay, Mysore, Bangalore, Hyderabad, Madras, Delhi, Agra, Kashmir, Calcutta, and Darjeeling. The total cost will be approximately £250 per person.

My primary objective in organising the tour is to stimulate full comprehension of India's vast potentialities in those persons who, through active work in their profession, are most favourably placed to strengthen the ties of friendship between Great Britain and India. Inquiries from doctors wishing to join the party should reach me before March 31.

R HINGORANI

METHONIUM COMPOUNDS IN HYPERTENSION

SIR,—Our cases of hypertension treated with methonium compounds now number 50, and many of them have been followed as outpatients for almost six months. Most of these were cases of essential hypertension with severe headache or left ventricular failure; 2 had had bilateral sympathectomy without benefit, and 1 had malignant hypertension.

Our method of administering the drug was to give 25 mg by injection intramuscularly and observe the blood pressure at fifteen minute intervals for the next two hours. If this initial dose was unsatisfactory it was increased by 10 mg or more and the procedure was repeated until we obtained what we felt was a satisfactory fall in blood pressure. The drug was then given by injection six-hourly, and as tolerance increased the intervals were reduced until in some cases the patients were having as much as 100 mg three-hourly. After seven to fourteen days on injection the patient was transferred to the drug by mouth. We considered that a suitable dose to commence with would be 250 mg by mouth at the same time interval as every 50 mg was given by injection. In some cases the patients had as much as 7–8 g daily by mouth.

Before any patient was started on methonium treatment he was given a fortnight's rest in bed, and his blood pressure was taken at frequent intervals during the day. When the patient was put on the drug his blood-pressure was taken even more frequently. All the injections were given with the patient sitting up, and a few patients were ambulatory. After four weeks in hospital all the patients were up and about. They were then seen as outpatients fortnightly or more often.

Since finding a case of bromide poisoning about five months ago we have estimated the serum-bromide level fortnightly on every patient receiving hexamethonium bromide. We found that every patient had a reasonably high serum bromide level, and owing to the slow excretion of bromide these serum bromide levels tended to increase at about the same rate irrespective of the dose of the drug, or at least provided the dose was between certain fairly wide limits. We have recently had a second case of bromide intoxication in a patient whose blood pressure did not fall in spite of the fact that he was receiving at one time 12 g of hexamethonium bromide by mouth.

Our results, which we hope to publish in detail shortly, have been unsatisfactory. Unquestionably injections of the drug, and in some few cases oral administration, will produce an acute fall in blood pressure. Sometimes, however, in spite of large doses of the drug even this acute fall did not occur. In all cases except 1, oral administration of the drug failed to keep the blood-pressure down, and every patient so far seen at outpatients has had a blood-pressure at the same level as it was before treatment was commenced, though many patients admitted to feeling much better. The initial fall in blood-pressure obtained with methonium compounds is often, in our experience, no greater than that produced in many patients by rest in bed.

We agree with the writers who have suggested that at present these compounds should only be used under hospital observation. The production of a drug which has a longer action than the hexamethonium compound and which does not contain the bromide radicle, or alternatively is effective in much smaller doses, would be the ideal to aim at.

Oldchurch Hospital
Romford, Essex

S LOCKET
Senior Physician

SIR,—After Kay and Smith[1] observed that the potency of the halide salts of hexamethonium given orally, expressed in terms of the cation, was highest for the iodide and lowest for the chloride, with the bromide intermediate, clinical studies of this drug have been made mostly with the bromide or iodide. It seems improbable, however, that the halide anion of such a salt, which must be completely dissociated in solution, can exert any significant effect on the activity of the hexamethonium cation, or even on its absorption. In view of the possibilities of bromism[2] and of iodism from the use of the bromide or iodide, we have been prompted to test the purity of some of the available preparations in order to determine whether the reputed inefficacy of the chloride was associated with any impurity, and to verify whether with pure salts the biological activity of the cation did indeed vary with the different halide ions. We have determined the halide content of samples of hexamethonium salts, and have assayed biological activity, using the antagonism of hexamethonium to the action of acetylcholine on the frog's rectus abdominis (limits of error 7–10%, $P = 0.05$). The results were as follows:

Hexamethonium salt	*Biological activity*	*Halide content (% theoretical)*
1 Iodide	95	94
2 Iodide	100	99
3 Iodide	100	100
4 Bromide	90	94
5 Bromide	100	99
6 Chloride	80	84
7 Chloride	97	99

Biological potency is given (in terms of the cation) as percentage of that of the pure iodide (Salts 2 and 3).

It will be seen that biologically several of the salts were below theoretical potency, and that in each case there was evidence of impurity. One particular cause of apparent inefficacy of the chloride came to our attention. We obtained a sample of chloride which had been made up as a powder in a waxed paper, in which it had remained for some months. On opening the paper no powder could be seen; but simple extraction of the paper with saline, followed by biological assay, produced 91% of the quantity of hexamethonium stated to be within the paper. The chloride therefore is sufficiently hygroscopic to take up so much water-vapour that it can go into solution and impregnate the wrapping paper.

We believe, therefore, that the results of Kay and Smith may have been due to a failure to give the full dose intended because of some impurity in the chloride

INTRAVENOUS IRON FOR ANÆMIA OF PREGNANCY

SIR,—I should like to thank Dr Scott and Dr Govan for their report last week on the use of intravenous iron therapy For the past year now I have been trying this method with cases which do not respond to iron by mouth, or where time was short The second condition is common in this practice because of unmarried mothers whom I do not have under my care until eight to six weeks before delivery

I am very pleased with the rapid response to this treatment, but I agree that occasionally a patient who has had other injections without a reaction may have a vasovagal attack In preventing local pain and reactions it is essential, in my opinion, that there should be no leakage from the vein For this I recommend that a very small (immunisation type) needle should be used and that the injection should be given very slowly indeed

York F CHARLOTTE NAISH

MUNCHAUSEN'S SYNDROME

SIR,—Dr Asher is to be congratulated on his timely description and apt christening of this curious syndrome Few hospital medical officers are unfamiliar with it, and with the extent to which its sufferers (for surely it is a disease) waste our already overtaxed hospital resources

One additional feature is that these patients usually present in hospital casualty departments either late at night or at weekends—times when young and inexperienced housemen are often left "holding the fort" At many hospitals these cases are so often seen that an unofficial register of them is kept, though its usefulness is vitiated because these patients seldom "try it on" at the same hospital twice, but go on circuit An accessible central register, at least in the London area, would be of the greatest value to casualty officers because once caught out these patients usually go, quietly and quickly The E B S. would seem to be the obvious place for such a register to be kept, reports being sent there from all local hospitals I believe that by this means the syndrome could be almost wiped out

The following case is atypical in that the patient did not take his own discharge

A 43 year old man arrived in the casualty department of St Giles' Hospital, Camberwell, at 8 15 P M on Jan 9, complaining of sudden onset of severe epigastric pain and vomiting Three upper and one lower abdominal scars were said to be due to operations on the stomach, gallbladder, and right inguinal hernia, one of these having been done at Mansfield Hospital in 1945 He was admitted with a provisional diagnosis of perforated peptic ulcer Although he had marked upper abdominal guarding and rigidity, gut sounds were heard, and there was no rise in temperature or pulse rate He was treated by continuous gastric suction, which he tolerated unexpectedly well

Inquiry revealed that he was never operated on at Mansfield Hospital A barium meal was entirely negative, and he was reassured and discharged on Jan 27, when he agreed that his pain was better

The same evening he arrived at Dulwich Hospital with the same story When he was on the point of being admitted, a nurse noticed a certificate of the same date from St Giles in his pocket A telephone call followed after which his pain mysteriously vanished and he left He was last seen walking down the road divesting himself of handfuls of tell tale certificates, evidently determined not to be caught out like that again

I wonder who's treating him now

St Giles Hospital,
London, S E 5

J E H STRETTON

SIR,—A good example of this syndrome was to be found in a ship's steward, of about 40, who haunted London hospitals about 1920 to 1934

He presented as a case of acute amœbic hepatitis, and he was able to produce just that element of "artistic verisimilitude" which could deceive at first the most experienced clinician, and which Dr Asher (Feb 10) mentions as a feature of the syndrome

His stay in hospital seldom lasted more than three days, and usually culminated in his throwing any convenient china utensil at the nearest nurse I met him first when he was admitted under the care of the late Dr F J Poynton at University College Hospital in 1920, pathological investigations had not got far when he threw a sputum mug at some unoffending nurse in the vicinity and was immediately discharged, though I cannot recollect whether we succeeded in dismissing him before he removed himself of his own accord.

I met him again about 1934 in St Mary Abbots Hospital, there having meanwhile been a number of interesting reports of his antics in other hospitals On this occasion, although amply forewarned, as a young admitting officer I was still not proof against his wiles and did not have the courage to refuse him admission, such refusal was not encouraged by authority and was apt to be followed by reproof In any case, I thought, after all the man *might* have a real hepatitis, one of those weird tropical diseases of which before the late war so many of us were ignorant On this occasion, however, I drew his attention to his previous unsatisfactory record of behaviour and besought him in his own interests to allow diagnosis and treatment, if required, to proceed The sequel was according to his usual form, he was admitted I think on a Friday and on Sunday morning the ward telephoned me as I was sitting down to lunch "Arthur has just thrown his dinner at a nurse!" (The plate was included in the missile) Before I could get to the ward he had taken himself off, gravy and potatoes on a nice clean apron were the only damage

I wonder if he is doing it still

Leamington Spa W M PRIEST

SIR,—From Dr Asher's graphic description in his article (Feb 10), it is clear that his first patient spent a few days in Oxford last May, after leaving St James' Hospital, Balham, and before his abdomen was explored at Harrow Hospital

He gave a name readily associated with "Beeches" and his age as 47, and was admitted to the Radcliffe Infirmary on May 9, 1950, with the symptoms of acute intestinal obstruction, and a scarred, distended tender abdomen There were, however, no fluid levels on a plain radiograph He gave a similar story, with a wealth of circumstantial detail, from having his "stomach blown to pieces" by a torpedo when chief engineer on the last ship from Singapore, to the eleven operations at Freemantle He explained the evidence of recent transfusions, presumably given at St James, as part of conservative treatment for a similar recent attack at sea, saying that his ship had docked only the previous night

He was treated conservatively, but his pain continued, this was unrelieved by pethidine, but was eased by injections of morphine or sterile water Next day he threatened to leave hospital as he considered that he had been insulted His distension and complaints increased, and a barium-enema examination was made – This showed a long filling defect in the rectum and sigmoid colon strongly suggestive of intussusception but on rectal examination nothing could be found to account for this It seemed that we had misjudged this suspicious character, and because of the well known danger of overlooking an organic lesion in such patients, operation was now advised He refused treatment, however, and was last seen on May 12 boarding a no 3 bus The following day his abdomen was explored at Harrow Hospital, as we have read, with no abnormal findings

The effect of anæsthesia on another recent patient with this syndrome was interesting

A nurse of 48, a known drug-addict, was admitted while convalescent from a compound fracture of her tibia with all the symptoms of acute intestinal obstruction. Her distended, scarred abdomen bore witness to six abdominal operations, and there was tenderness in the left iliac fossa. There was no evidence of nerve damage. Although bowel sounds were increased, and there was gaseous distension on a plain radiograph, there were no fluid levels. After the induction of anæsthesia and without the passage of flatus her abdomen became soft and flat. She was allowed to regain consciousness, and as she did so her uncovered abdomen appeared rapidly to swell. This seemed to be due to contraction of her diaphragm and lateral abdominal muscles rather than to aerophagy. She seemed disappointed that an operation was not considered necessary, and for a time continued to complain of pain. A barium series was normal, and she was discharged a few days later, still with apparent distension.

Radcliffe Infirmary, Oxford. NEIL WARD MCQUAID

SIR,—A woman of 45 was admitted to this hospital on Feb. 14, complaining of a fæcal fistula. She gave a history of eighteen operations, all performed at the Royal Devon and Exeter Hospital, and said that for the last four days there had been a profuse discharge of foul dark material from an ulcerated area in the lower abdomen. It was not until we read Dr. Asher's article that we realised exactly what we were dealing with. When she received no operative treatment she became very resentful and was discharged the day after admission.

Lambeth Hospital,
Brook Drive, S.E.11.

J. WILKS
Surgical Registrar.

SIR,—To assist recognition of Munchausen's syndrome, may I recommend an old Barts custom. For generations the Barts surgery has possessed a "black-book" in which descriptions of such hardy annuals are entered. From it casualty officers have derived assistance, and readers have derived much amusement.[1]

My first encounter with this disease (sub species, laparotomophilia) fooled me completely. But the second time he was entered in the black book and introduced to the casualty porter, who was told to remember him in future. Three years later he again deceived a new houseman, and was enjoying a very thorough abdominal examination in casualty, when the same porter looked through the screens. He was instantly recognised by the patient who shouted "Blimey, it's you again," and bolted into the street like a startled hare. I do not know the subsequent history of this patient, but it might have been of interest because his trousers remained on the couch.

London, W.8. JAMES T. HAROLD

RESULTS OF SURGERY IN SCIATICA AND LOW BACK PAIN

SIR,—In their interesting article of Feb. 3 Mr. Burns and Mr. Young make two statements which, in my opinion, are not entirely correct—namely, that it is usually impossible to foretell which of the lower two discs is affected, and that at operation it is essential to explore both discs. I agree that it is usually impossible to foretell, from orthopædic or neurological *signs*, which of the lower two discs is affected; but surely this can often be decided, before starting the physical examination, from the distribution of the sciatic pain? This, of course, does not apply to patients with low back pain only. The majority of patients, if carefully questioned, localise the sciatic pain accurately to the distribution of the 5th lumbar or 1st sacral nerve-root; pain due to protrusion at the 4th disc is situated mainly on the lateral side of the buttock in the region of the greater trochanter, down the lateral aspect of the limb, and in front of the lateral malleolus, whereas pain due to protrusion from the 5th disc is on the medial side of the buttock in the region of the ischium, down the posterior aspect of the limb, and behind the lateral malleolus.[1]

It is hardly necessary to emphasise the great value of a careful neurological history about the pain (which is usually the only complaint and sole reason for treatment), its distribution, how it has affected the patient's life, and the result of previous treatment. This information not only provides the main considerations in deciding treatment, but, at the same time, it gives a better guide than physical signs to the level of the protrusion.

When the pain is localised accurately to a typical root distribution, as in the majority of cases, only the affected disc need be explored; it is certainly not essential to explore both 4th and 5th lumbar spaces.

Leeds. W. R. HENDERSON

BIRTHMARKS AND MOLES

SIR,—Your annotation of Jan. 20 is of interest and importance. Since there is still no general agreement on the treatment of the common (or "cavernous") hæmangioma of infancy and childhood, I investigated their natural history by leaving a series untreated in 1945–46 (thus repeating the experiment of Lister[1]) together with a control series treated by the usual radiation methods.

Lister's findings were confirmed; of 83 cases followed for three years 45 (54%) regressed spontaneously, and of 69 followed for five years 66 (96%) had more or less disappeared. Radiation or other treatment can make them disappear faster; but this is usually unnecessary and therefore may well be considered undesirable unless there are positive reasons for treatment.

These results were communicated to the fifth International Congress of Radiology in London last year, and I hope to publish the full details before long.

Sheffield National Centre
for Radiotherapy.

J. WALTER

BEDPAN EXERCISE

SIR,—Your annotation of Jan. 27 does not refer to the type of bedpan under observation. The slipper model, which can be slid beneath the recumbent patient, is much less exhausting for females who (since they cannot use a bottle) may need to hop on and off the conventional type several times in the day. It is also easier for the nurse.

London, N.W.1. STELLA CHURCHILL

ELECTRIC POWER SHORTAGE AND HOSPITAL PLANNING

SIR,—During the last twenty years, at least, a trend has been apparent in hospital design, in the direction of greater concentration in higher buildings. Much can be said in favour of this, and something, also, against it; but all I wish to do in this letter is to call attention to the bearing on the question of a new factor, or at any rate of a factor which has forced itself on our notice. The higher the building the more is it dependent on lifts and the more paralysing is the effect of a failure of electric power. A two-storey hospital without the use of its lifts suffers nothing much worse than serious inconvenience; even a three-storey one can struggle along; but the mere thought of a hospital of six or more storeys deprived of its lifts makes one shudder. Hitherto, the risk of anything worse than rare and brief failures of electric power has been remote enough to be taken without much misgiving; but now there seems to be reason to fear that we have entered upon an era of recurring power shortage, possibly getting worse as time goes on. The bearing of this on hospital design has therefore become a matter calling for serious consideration.

The question may seem a little academic at present, when the prospect of building the much needed new hospitals seems to be moving into an ever more distant future with each year that passes. It would, however, be well to take advantage of the period of enforced inactivity, to discuss such questions and be ready with conclusions, in case happier times ever come again

---

London T S McINTOSH

TRAINING OF INVALID CHILDREN

SIR,—In Prof Alan Moncrieff's address to the 62nd annual general meeting of the Invalid Children's Aid Association (*Lancet*, 1950, ii, 494) he remarked that "the state of civilisation of a community can be deduced from the way it looks after its lame ducks—and ducklings" This statement raises many important issues on which I would like your readers' advice What is the best way of looking after lame ducklings? In your report of the meeting you say that an appeal for £15,000 was made for a holiday home for invalid children, but that it had previously been disclosed that the I C A Association has an overdraft of about £12,000 and the excess of expenditure over income last year was £3000 Working in a country where many services for lame ducklings require development, I wonder how far it is justifiable to expend the time and energy of skilled workers and public money on children who can never utilise the training they receive All that these invalid children require is someone to care for them and make them happy, and I feel sure this could be done on a more economical basis than the one now recommended, though I would welcome the opinion of your readers on this subject In Malaya most of these children are cared for in their own homes, where some are well and others less well looked after, but the majority seem happy I have no hesitation in recommending training for the blind and deaf and for certain classes of cripples who can become useful citizens, but what of the others?

General Hospital, Penang, Malaya. C ELAINE FIELD

TREATMENT OF THE AGED SICK

SIR,—In his letter last week Dr Brown refers to senile mental changes as a reason for a patient being confined to bed Has he considered the other aspect of senile patients in this relation—confinement to bed as a cause of senile mental changes, ranging from exaggeration of normal involution to the "vegetable" state? Lord Amulree and his colleagues (Jan 20) do in fact mention the desirability of keeping the elderly patient mobile for physical, as distinct from mental, reasons

I feel that the relation between enforced bed rest and mental deterioration is not adequately stressed in our teaching or practice In my opinion the mental failure is a direct result of the lowered blood pressure, which follows rest, failing to force blood through the smaller cerebral vessels The fact that visitors to the bedfast patient steadily decrease in numbers as the months and years go by, with a consequent reduction of the stimulus and outside interest which they afford, is a recognisedly important factor, but it is not nearly the whole story

Blackrock, co Dublin JOHN F FLEETWOOD

SIR,—As one of those concerned with the care of the aged sick, I found Lord Amulree's article (Jan 20) interesting but somewhat disappointing In his survey he failed to mention that important clinical entity—the aged psychiatric patient In my experience the ambulant senile confusional patient presents one of the major problems in geriatrics, but one that must be tackled if we envisage a comprehensive service in this branch of medicine

It is hoped to publish shortly the results achieved in the psychiatric department attached to the geriatric unit at this hospital These results should prove encouraging, and help to illuminate a dark corner in geriatrics

Geriatric Unit J DE LARGY
Langthorne Hospital London E 11 Senior Medical Officer

Public Health

Smallpox

WHEN S S *Strathmore* arrived from Australia in the Port of London on Feb 12, a 12 year-old girl passenger, who had embarked at Bombay on Jan 26 was removed to St Andrew's Hospital annexe, Billericay, Essex, where she was diagnosed as smallpox She was admitted to Long Reach Hospital, Dartford, on Feb 14

She had sickened on Jan 28, and a rash appeared on the 30th On that day she was isolated in the ship's hospital as a case of chickenpox She was admitted as such to the hospital in Essex, but on Feb 13 a review of the case and information that she had previously suffered from chickenpox led to a suspicion of smallpox. She had been vaccinated in infancy (two scars) and again before leaving India The recent vaccination was unsuccessful

S S *Strathmore* called at Aden on Jan 30, Suez on Feb 2, Port Said on Feb 3, and Marseilles on Feb Up to Feb 20 there had been no further reports of smallpox or suspected smallpox among the passengers and crew

Influenza

In England and Wales during the week ended Feb 10, influenza deaths in the Great Towns fell from 61 2 to 41 7 per million The number of deaths fell most steeply in the East and West Ridings, the North Western, North Midland, Midland, Eastern, London, and South Eastern regions, and in Wales There were smaller decreases in the remainder except the Northern region where there was an insignificant increase of 2 deaths The proportion of influenza deaths in the age-groups 55 and over rose to 91 5%

In the Great Towns pneumonia deaths fell from 830 (last week) to 662 Pneumonia notifications in England and Wales also fell from 3513 (last week) to 3091

In London there was a continued decline in the number of removals to hospital for pneumonia, influenza, and bronchitis, as also in pneumonia and influenza deaths

Weekly claims on the National Insurance funds for the week ending Feb 6 continued to fall There were 288,940 as against 350,714 the previous week

Influenza Abroad —There is evidence of a high prevalence of influenza in certain parts of Canada, which is understood to be due to virus A-prime It is now reported that cases in the Yugoslavia outbreak have been due to virus B, and that virus A-prime has been identified in Italy The disease is also reported in Germany, but the viral type has not, as far as is known, yet been established

Poliomyelitis

In England and Wales notifications of poliomyelitis during the week ended Feb 10 were as follows paralytic 12 (21), non-paralytic 7 (11), total 19 (32) Figures for the preceding week are in parentheses The total is the lowest since the week ended April 8, 1950

Difficulties in the School Health Service

In his report for 1949 on the school health service in Worcestershire, Dr Wyndham Parker, the county and school medical officer draws attention to three difficulties

1 *Dental Service* —As elsewhere in the country, the difficulty of retaining the school dental staff has become acute "Efforts have been made to try to maintain the service by approaching private dental practitioners, but the results in this connection have been small to date"

2 *Hospital Treatment* —Information is no longer readily available, as it was when the county council, through its education committee, paid for such treatment 'Reports are irregular and often very delayed"

3 *Specialist Service* —Specialists, notably ophthalmologists and to a lesser extent orthopædists, are now so busy with other duties that the school health service has had to take second place

Obituary

HORACE MIDDLETON VERNON
M.A D.M Oxfd

Dr H M Vernon for many years a member of the ientific staff of the Industrial Health Research Board as a pioneer in the application of scientific method and search to the problems of the conditions affecting ose who work in factories

Born in 1870 he was educated at Dulwich College and erton College, Oxford to which he obtained a science cholarship In 1891 he took first-class honours in the hemistry and physiology schools. As an added interest e studied biology and with a biological scholarship in 894 he worked at the Marine Biological Station at Naples, where he specialised in a statistical study of the effects of environment and cross fertilisation on the growth of sea-urchin larvæ He obtained the Rolleston prize the George Henry Lewes scholarship and a Radcliffe travelling fellowship, and he held a university lectureship in chemical pathology before taking his medical degree in 1898

Shortly afterwards he was elected to a fellowship at Magdalen College, Oxford which he held till 1920 There he settled down to teaching and research work in physiology But the 1914–18 war diverted his interest and he became for a time a worker in a munition factory in Birmingham His medical and scientific training opened his eyes to the environmental problems of industrial workers When the Health of Munition Workers Committee was appointed in 1915 to study the human problems of the industry Dr Vernon was one of the first investigators appointed His early work on hours of labour has been of great practical importance, and he also introduced a method of studying the effects of hours of work on health and output These findings were embodied in his official memoranda on Industrial Efficiency and Fatigue in Munition workers published between 1915 and 1918

When the Industrial Fatigue (Health) Research Board was instituted at the end of the war, Dr Vernon was offered a post The rest of his working life was spent in research concerned with tinplate workers, blast-furnace workers and coalminers particularly from the point of view of atmospheric conditions heating and ventilation in potters shops, rest pauses accidents, and allied subjects

After he retired in 1932 he occupied himself in writing and he also found more time to watch the cricket matches which he so greatly enjoyed Apart from articles in scientific journals he published in these years authoritative books on *The Principles of Heating and Ventilation* (1934) *The Shorter Working Week* (1934), *Accidents and their Prevention* (1936), *Health in Relation to Occupation* (1939) All these works show clearly how Dr Vernon s scientific training both in the organic and inorganic field helped him to recognise allied problems in a different field and gave him the tools with which to collect and analyse his data He died on Feb 11 after a long life spent in work he loved

Dr Vernon married Miss Katharine Ewart She survives him with a son and three daughters

CHARLES PYE OLIVER
C.B C.M.G M D Lond., D P.H

Dr Pye Oliver who died on Jan. 28 in his 90th year, had served Maidstone as a townsman and a doctor for well over half a century His family had a tradition of civic service for his father Dr J Oliver, was an alderman and mayor of Maidstone

Dr Oliver received his medical education at Charing Cross Hospital and University College Hospital As soon as he obtained the L.S.A. in 1885 he started in practice at Gabriel s Hill, Maidstone, but he continued with his studies and he obtained in turn the Conjoint qualification in 1887, the M B in 1888, and the M.D in 1892 His interest in public health had already been aroused and in 1896 he took the D P H. and his M D in State medicine in 1902

Meanwhile in 1899 he had been appointed medical officer of health for Maidstone Contemporary interest in raising standards of health and hygiene gave him opportunities which he was quick to seize, and he started the maternity and school medical services of the town on a sound foundation Besides these official duties he acted as physician to the West Kent Hospital, in addition to running his practice, and in these early days most of his visits were paid on horseback

As early as 1887 he had joined the Old Maidstone company of the Volunteer Medical Staff Corps Later he became surgeon of the corps and eventually succeeded to the command with the rank of major He represented the corps at the funeral of Queen Victoria In 1913 he was appointed honorary surgeon to the King for his work for the field ambulance service in Kent

During the 1914–18 war he served in France with the 67th division and he was three times mentioned in despatches Later he became A.D.M S of the 67th division and the 23rd Army Corps In 1918 he was appointed C.M.G and in 1927 C B After the war he continued his association with the Regular and Territorial Armies and he became honorary colonel of the R.A.M C units of the 44th division of the Territorial Army

Dr Oliver worked for his county as well as his town and in 1920 he became a J.P for Kent, sitting regularly on the Bearsted bench In 1931 when he retired he was appointed a deputy lieutenant of the county During the late war though he was in his 80s, he was county controller of the V.A.D , and he also worked for the British Red Cross Society and the Order of St John of Jerusalem

Since 1919 Dr Oliver had been a widower, but he leaves four sons and one daughter A son has followed his father in practice in Maidstone.

Dr ALBERT JACOBUS STALS the South African minister of health and social welfare who died at Cape Town on Feb 5, was a graduate of medicine and law of the University of Dublin. He qualified in 1909, taking his M D the following year He was a member of the South African parliament from 1924 to 1933 and again from 1943 onwards Dr Stals was made minister of education and of health and social welfare when the Nationalist government was formed in 1948, but he gave up the portfolio of education in 1949

Notes and News

APPROVED NAMES FOR DRUGS

The British Pharmacopœia Commission have added five approved names to the supplementary list they published last year (*Lancet* 1950, ii, 422)

Approved names	*Other names*
Paramethadione	5 Ethyl 3 5 dimethyloxazolidine 2 4 dione Paradione
Ethopropazine	N (2 Diethylamino *n* propyl) phenothiazine Lysivane is the hydrochloride
Diethylcarbamazine	1 Diethylcarbamyl 4 methylpiperazine Banocide is the dihydrogen citrate Hetrazan is the dihydrogen citrate
Lucanthone	1 2 Diethylaminoethylamino 4 methyl thiaxanthone Nilodin is the hydrochloride
Solapsone	Tetrasodium 4 4 bis (γ phenylpropyl amino) diphenylsulphone α γ α γ tetrasulphonate Sulphetrone

TUBERCULOSIS

"I do not admit of pessimism, but optimism is difficult," a correspondent recently wrote to Sir John Charles, chief medical officer of the Ministry of Health In quoting the letter at the annual luncheon of the Joint Tuberculosis Council, on Feb 17, Sir John remarked on his own different outlook "I do not admit of complacency, but pessimism is difficult" Since July 5, 1948, he said, over 3500 tuberculosis beds have been added to the complement in England and Wales, and further additions are expected in the next six months, in the past year whole time tuberculosis nurses have increased by 700, and part time nurses by 150, B C G vaccination is now well established, 30,000 people having received it already, and an immunisation rate of 5000 a month is contemplated in the near future Since the start of the National Health Service the number of mass radiography units in action has risen from 30 to 60, and some 1½ million people are now being examined yearly

Dr Peter Edwards, the chairman, in answer to Sir John Charles's toast of The Council, made a rallying reply on the recent mitosis at the Ministry Sir Robert Young, in a kind and elegant speech, proposed the toast of The Guests, and Dr Hugh Clegg, replying, related a parable Two skeletons, he said, hanging in a remote corner of an old mansion, were arguing about their situation "Say what you like," one of them finally declared "if we had any guts we could get out of this —— cupboard"

MEDICAL GAS CYLINDERS

A further meeting of the Conference on Medical Gas Cylinders was convened by the Association of Anæsthetists on Jan 24 The conference received a report that provisional agreement had been reached between representatives of the United Kingdom and the U S A, at a meeting of the International Standards Organisation, regarding the introduction of certain colour markings and of non interchangeable couplings for medical gas cylinders, with a view to eliminating the possibility of using the wrong gas The agreement requires ratification by the appropriate bodies in each country This is now being sought, and it is hoped that these proposals, which have been accepted by the International Standards Organisation, will soon take effect

TOXIC SPRAYS

The *Manchester Guardian* (Feb 16) reports that the National Farmers' Union have recommended that farmers using toxic sprays should ensure that

Operators wear protective clothing

Proper facilities for washing are provided near the scene of spraying operations

Limits are placed on the period of work each day and the total period in each week

Adequate supervision of workers using toxic substances is made

No food or drink is consumed within the spraying zone

Proper decontamination of machinery and equipment is carried out immediately after use

Attention was drawn last year to the dangers of some of the newer insecticides by Dr James Wilson, secretary of the American Medical Association's council on pharmacy, and by Dr Donald Hunter in his Ernestine Henry lecture to the Royal College of Physicians (*Brit med J* 1950, i, 449, 506, *Lancet* 1950, i, 407)

WEST LONDON RHEUMATISM DEPARTMENT

More than a thousand new patients are seen each year at the West London Hospital's department of rheumatic diseases, and the department's attractively designed report for 1950 illustrates the many different activities of workers in this field The papers published in the report include a lecture given by Prof Philip Hench when he visited the department, an account of a tour in America by one of the staff, and the diary of a patient with rheumatoid arthritis while under treatment with "Cortisone" and A C T H

DIRECTORY OF INTERNATIONAL SCIENTIFIC ORGANISATIONS

Details of the aims, facilities, publications, and governing bodies of more than 150 international scientific bodies are given in this Unesco handbook, which is now available at H.M. Stationery Office (6s) The organisations are grouped under three headings basic sciences, applied sciences, and the ever hospitable "miscellaneous" Medicine takes its place among the applied sciences, and 59 organisations are listed The handbook offers a great deal of information, not otherwise readily accessible, in a convenient and readable form

OFFICE ROOMS NEEDED

The British Epilepsy Association, founded last year as a memorial to Dr Tylor Fox, has made good progress So far it has been housed in the building occupied by the National Association for Mental Health, but there is only room for one worker in the space available, and the time has now come when the British Epilepsy Association needs clerical staff if its plans are to develop The honorary secretary asks for news of one or two office rooms in a central position, and at a moderate rent, which might be suitable for this young and growing body Anyone able to suggest appropriate quarters is asked to write to Miss Irene Gairdner, at 30, Queen Anne Street, London, W 1

PROSPECTS IN THE DESERT

"If ye be willing and obedient, ye shall eat the good of the land, but if ye refuse and rebel, ye shall be devoured with the sword for the mouth of the Lord hath spoken it" Thus wrote Isaiah over 2600 years ago

Today the prophets exhort us to apply scientific principles and techniques to farming throughout the world, that we may become well fed and prosperous, otherwise we shall die in our millions of starvation and in the civil wars and epidemics that accompany famine The message is clear and simple, if we die, it will not be for lack of forewarning The chief prophet Lord Boyd Orr, speaks to the world with the full vigour of stern Scottish evangelism, minor prophets follow with varying success Among these Ritchie Calder with his new study of desert civilisations,[1] is assured of a high place Calder was asked by Unesco to investigate the problem of developing for human use the vast desert surfaces of our planet He limited his study to the deserts of North Africa and the Middle East, visiting Algeria, Tunisia, Tripolitania, Cyrenaica, Egypt, Iraq, Iran, Israel, and Cyprus He used every ancient and modern means of transport and was accompanied only by Raymond Kleboe, whose beautiful photographs help towards a proper understanding of the book Calder has a sense of science and a sense of history and also a peculiar appreciation of values in a civilisation From all his cameos there stand out in close association the art and skill of the water engineer, the efficiency of the farmer, the health and energy of the people, and the level of their culture Throughout history these are intimately interwoven, and there seems no escape from the conclusion that water engineering was and remains the foundation on which all our high civilisations ultimately stand If the water engineer fails, then mankind cannot prosper and the arts die

Calder gives his message simply, even ruthlessly, but the breadth of his knowledge and the sureness of his judgments make the book fascinating and exciting Although in most places he visited the state of agriculture and the condition of the people was poor and often pitiable, yet in every country he met a few scientific people captivated by the desert and confident that much of it could be reclaimed for agriculture Applied science has already yielded impressive results. There is, for example, the great work of the Jewish collective settlements (kibbutzim) in bringing the deserts of Palestine back into cultivation and also the successful banishment of alaria from Cyprus The book ends with the words of an d French Colonial officer, just about to retire on parting om Calder in the Kasserine Gap 'Tell me that there are the world ten men who believe that the desert can be made blossom—ten men who believe that we can redeem the upidities of mankind—and I shall die happy

niversity of London

The governing body of the British Postgraduate Medical ederation has awarded travelling fellowships for 1951–52 enable for one year to W A Briscoe B.M., of the Post raduate Medical School of London (respiratory function, S.A), H. McK. Carey, M B., F.R C S.E , M.R C O G , of the nstitute of Obstetrics and Gynæcology (uterine physiology, anada and U S A.) J A Carr, F.R.C S , of the Institute f Urology (calculus formation, U S.A.) , J O Laws, M.R C.P , f Guy s Hospital Medical School (cytology France) , R B ynn, M.D F.R.C S , of the Postgraduate Medical School of ondon (cardiovascular surgery, U S.A.)

niversity of Birmingham

Dr A. P Thomson professor of therapeutics in the university has been appointed dean of the faculty of medicine in uccession to the late Sir Leonard Parsons

University of Manchester

The Queen will attend a congregation to be held on May 13 n celebration of the centenary of the Owens College, to eceive the honorary degree of LL.D The other graduands will include Sir John Stopford F R.S vice chancellor of the university since 1934

Royal College of Surgeons

At a dinner held on Feb 14, to mark the 223rd anniversary of John Hunter s birth, Mr H A. Marquand, the new Minister of Health, said that a great opportunity lay before him. The transfer of responsibility for housing to the Ministry of Local Government and Planning left him free to concentrate on the health services as could no Minister since Mr Lloyd George formed the department in 1919 with Lord Addison at its head. (Lord Addison, a fellow of the college was present at the dinner) Mr Marquand declared that his aim was to learn, not only about the National Health Service and its various institutions but also about the traditions of the medical and allied professions With his university background he would be especially sympathetic towards claims for medical education or research and he appealed for the coöperation of all doctors to build up a service that would be of real value to the people Mr Marquand was proposing The College and in his reply Sir Cecil Wakeley the president dwelt on the activities of the past year In 1950, he said the law decided that the college was a charity and that the Middlesex Hospital was not nationalised, while in 1951 the law decided that the Middlesex Hospital was nationalised and the college was not a charity [*Lancet* 1950, ii, 155 , Feb 17, 1951, p 405] 'Very perplexing ' the college at any rate is not letting its uncharitable status pass unchallenged and is taking the question to the House of Lords ' Turning to examinations Sir Cecil remarked that an agreement for reciprocity of primary fellowship examinations had been reached by the three Royal Colleges of Surgeons and the Royal Faculty of Physicians and Surgeons of Glasgow ' This arrangement will alleviate the hardship caused to men who at present feel the need to pass more than one primary examination while still not in a position to know which fellowship they will eventually wish to hold As to finance, the college, with great projects in hand had its anxieties a further £400 000 or so was needed for building alone In replying for The Guests to a toast by Prof Ernest Finch the Archbishop of York owned that he had found some difficulty in briefing himself for a well known book of quotations cited among many references to surgeons, only one that was laudatory Mr P H Mitchiner proposed the Hunterian Orator and Sir Max Page, this year s orator replied

University of Sheffield

Dr C M Scothorne has been appointed honorary demonstrator in bacteriology, Dr Cedric Harvey clinical teacher in child health, and Dr J Walter clinical teacher in radiology

Royal College of Physicians of London

Prof K. J Franklin will deliver the Oliver-Sharpey lectures on Tuesday and Thursday, March 13 and 15, at 5 P.M at the college, Pall Mall East, S W 1 He is to speak on Aspects of the Circulation s Economy

Ministry of Health

The Minister of Health Mr H. A Marquand M P , has appointed Mr A. R W Bavin to be his principal private secretary, and Miss L R Prescott to be his assistant private secretary

Harveian Society of London

Sir James Learmonth will deliver the Harveian lecture to this society on Thursday March 15, at 8 15 P.M. at the Royal College of Surgeons, Lincoln s Inn Fields, London, W C.2 He is to speak on the Surgery of the Spleen

Ulster Pædiatric Society

At a meeting of this society on Feb 7, with Dr Rowland Hill in the chair Dr Joan Logan spoke on Renal Acidosis, Dr R J Young on Cystic Disease of the Lung Dr A. W Dickie on B C G Vaccination in Tuberculous Families in Sweden

Ophthalmologists Fees

At a meeting on Feb 9 the N O T B Association unanimously resolved that they could not accept the validity of a reduction in the fee for medical examination through the supplementary ophthalmic service to £1 They held that any fee below 25*s* was inequitable and would not be accepted save under duress The association is circularising all its medical members giving full particulars of the stand taken

Kingston Victoria Hospital

After discussions between the Minister of Health and a deputation led by Mr J Boyd Carpenter, M.P , on the plan to convert the Kingston Victoria Hospital from a general hospital into a gynæcological unit the following agreed statement was issued

> The Minister explained the general proposals of the south west metropolitan regional hospital board which have led to the present situation Members of the deputation put a number of points to the Minister and the Minister undertook to consider these points

A New Chair at Yale

Dr J F Fulton has retired from the chair of physiology at Yale to accept a new appointment, also at Yale as Sterling professor of the history of medicine It is expected that Dr Fulton will develop a small university department in the field of the history of medicine and science in the historical division of the Yale medical library He will have an honorary appointment in his old department and will continue with certain phases of physiological research important for the present war emergency

Slimming on Television

For the next three to four months viewers will be able to watch the progress of two women who are taking part in a slimming experiment under the supervision of Dr David Edwards of University College Hospital On Feb 27, a television cookery expert will discuss a special diet and Dr Edwards will explain the medical aspects of slimming The two women will appear in future *Designed for Women* programmes, when they will be weighed and measured and will describe their reactions to the diet

£1000 to be Recovered from Dentist

Mr Hector McNeil Secretary of State for Scotland, has directed the Executive Council for Ayr County to recover £1000 from a dentist The dental service committee had found that in treating six of his patients this dentist had failed to employ proper skill and attention. His offences included failure to undertake fillings which were obviously necessary, and proposals to carry out multiple extractions and to provide full dentures in excess of the treatment required Four of the six patients he failed to advise as to the whole treatment necessary He also failed to produce records when asked for them by a dental officer of the Department of Health , and he admitted that all his records had been destroyed

Society of Chiropodists

The annual convention of the society will take place on April 26, 27, and 28, at Friends House, Euston Road, London, N W 1 Sir Henry Cohen will open the convention, and other speakers will include Lord Amulree and Mr T T Stamm

Association of French-speaking Pædiatricians

The association will hold its 13th congress at Algiers from May 7 to 9 Further particulars may be had from the Expansion Scientifique Française, 23, rue du Cherche Midi, Paris, VI

International Congress of Gynæcology

To celebrate their jubilee the French Society of Gynæcology, in collaboration with UNESCO, are holding an international congress at the Centre Marcellin Berthelot, 28 bis, Rue St Dominique, Paris, from June 23 to 29 Further information may be had from Dr Maurice Fabre, secretary general, 1, rue Jules Lefebvre, Paris, IXe

South African Minister of Health

Dr Karl Bremer has been appointed South African minister of health and social welfare in succession to the late Dr Stals Dr Bremer obtained his M B degree at Cape Town University in 1935 and his F R C S in 1938 On his appointment as minister he resigned from the presidency of the South African Medical Council, an office which he had held for many years

C M F /M E F Physicians' Reunion Dinner

This dinner will be held this year in the hall of the Royal College of Physicians of Edinburgh on Saturday, May 12 Any physician who served in these Commands during the war should write to the Edinburgh secretary, Dr R W D Turner, 20, Warriston Crescent, Edinburgh

South Wales Medical Ex-Service Association

This association will hold their annual reunion dinner on Saturday, March 3, at the Park Hotel, Cardiff, at 7 45 P M Colonel D P Holmes will be in the chair Tickets (12*s* 6*d*) may be had from the hon secretary, Mr C W D Lewis, surgical unit, Royal Infirmary, Cardiff

The Minister's Reception

On Friday last Mr Hilary Marquand, the Minister of Health, held a reception at the new office of his Ministry in Savile Row The move from Whitehall, where the Ministry's present offices will be occupied by the Minister of Local Government and Planning, is taking place gradually over the next few weeks

London Hostel for Tuberculous

At the end of last year the Ministry of Health approved in principle of the London County Council's proposal to provide hostel accommodation for people with tuberculosis who are infectious but are unlikely to benefit by further sanatorium treatment and who have no suitable home of their own (see *Lancet*, 1950, ii, 779) The L C C announce that they are now setting up a hostel of this kind for 35 men in Islington

World Health Organisation

Japan has applied for full membership in W H O The application has been placed on the agenda of the World Health Assembly due to open on May 7 in Geneva According to the W H O constitution, States not belonging to the United Nations can be admitted as members by simple majority vote of the assembly To date, 74 countries have joined W H O and one country, Southern Rhodesia, has been admitted as an associate member

---

Mr C Price Thomas, under the auspices of the British Medical Association and the British Council, is spending two weeks in Yugoslavia lecturing and giving demonstrations of the surgical treatment of tuberculosis He is accompanied by Dr Robert Machray and Mr Peter Jones

The Royal Society for the Prevention of Cruelty to Animals has issued the 7th edition of its booklet on First-Aid and Fire Precautions Copies may be obtained, price 6*d* , from the society, 105, Jermyn Street, London, S W 1

CORRIGENDUM : *Potassium Deficiency in Idiopathic Steatorrhœa* —Dr Lubran and Dr McAllen inform us that in the report on the blood chemistry of their patient (*Lancet*, Feb 10, p 321) the figures for sodium should have been 301 mg (130 9 m eq), for calcium 7 6 mg (3 8 m eq), and for phosphorus 3 2 mg (1 8 m eq)

SOME RECENT STUDIES OF PORPHYRIN METABOLISM AND PORPHYRIA[*]

C J WATSON
M.D., Ph.D Minn., F.A.C.P
ROFESSOR OF MEDICINE UNIVERSITY OF MINNESOTA MEDICAL SCHOOL AND HOSPITAL, MINNEAPOLIS

I HAVE chosen the subject for this lecture with a very real sense of humility, having in mind the many outstanding contributions made by London porphyrin cholars over the last half century I am the proud ossessor of a reprint from THE LANCET of Sir Archibald arrod's Bradshaw lecture for 1900 on the Urinary igments in their Pathological Aspects This contains remarkable number of interesting observations on what as then mistakenly termed hæmatoporphyrin, now alled coproporphyrin The more recent studies in this eld by London investigators, notably Rimington Harrison, Gray, and Prunty and their associates, have rovided a great stimulus to all who, like myself, are nterested in the clinical and fundamental aspects of the porphyrins

CLASSIFICATION

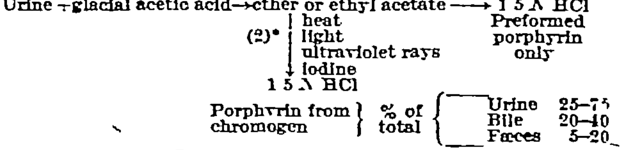
It is perhaps not surprising that the earlier studies of he porphyrins confused the artificial hæmatoporphyrin with those which occur in Nature This difficulty may be scribed at least in large part to the relatively crude pectroscopes available at the turn of the century, hese were too insensitive to detect the slight differences n absorption spectra especially between hæmatoporphyrin and coproporphyrin, whose spectra are almost dentical. Hans Fischer was the first to put this matter on a firm footing, by crystallising the more important of he naturally occurring porphyrins and clearly establishing their identity on the basis of various physical criteria Fischer 1915, 1930, Fischer and Orth 1937) Coproporphyrin, so called because it was first found in the æces, was noted to be ether-soluble, whereas uroporphyrin, first isolated from the urine, was insoluble in ether The most widely represented porphyrin, that of the hæmoglobin molecule and of other iron porphyrin enzymes, was appropriately named protoporphyrin This was also found to be ether soluble, but easily separated from coproporphyrin by being extracted from ether only by more concentrated hydrochloric acid, by exhibiting an insoluble sodium salt, and by chloroform solubility

Fischer (1930) recognised a "dualism" of the porphyrins in Nature—i e , the existence of two isomeric series which he believed to be synthesised independently, a concept which has been fully borne out by subsequent work The classification of the porphyrin isomers depends on the four artificial ætioporphyrins prepared by Fischer and his associates The structural formulæ are given by Fischer and Orth (1937) and Watson and Larson (1947), and it will suffice to recall now that the ætio porphyrins have only methyl and ethyl groups on the eight positions of the four pyrrol nuclei, the latter being joined by methene (CH) bridges to form the porphyrin ring There are but four possible differing combinations, and hence isomers, of the ætioporphyrins The proto porphyrin of the hæmoglobin molecule corresponds in configuration to ætioporphyrin III, and, as we shall note in a moment, there is also a type III coproporphyrin which is probably of considerable importance in hæmoglobin metabolism Coproporphyrin I differs only by reversal of the side groups on pyrrol nucleus IV This difference, nevertheless, is such that type I could not be derived from type III without complete disruption and resynthesis, hence the formation of type I is generally regarded as an independent synthesis Types II and IV have not so far been encountered in Nature, either as a coproporphyrin or any other form of porphyrin Sufficient data have now accumulated to indicate the unlikelihood that either II or IV will be found, and it is now reasonably clear that the enzyme systems necessary to porphyrin formation relate only to types I and III Uroporphyrin I has four acetic acid groups instead of the four methyl groups of coproporphyrin, since it also has the four propionic acid groups it is an octacarboxyl porphyrin, whereas the coproporphyrins are tetracarboxyl. The question of occurrence of a uroporphyrin III will be considered subsequently

URINARY EXCRETION

The study of the urinary excretion of coproporphyrin has been based mainly on fluorimetry, because the porphyrins generally exhibit an intense red fluorescence when exposed to light of about 4000 Å Various modifications of Fikentscher's (1932) method have been proposed In all of them it is assumed that any porphyrin excreted as chromogen or leuco-compound is converted to porphyrin during extraction and purification Recently, however we have "rediscovered" a fact that was undoubtedly known to Saillet (1896), although his terminology and description were somewhat obscure Saillet recognised that his "urospectrine" or "urohematoporphyrine normal" occurred in part in the urine as a colourless chromogen which was not readily extracted from ether or from ethyl acetate by hydrochloric acid. There appears to be little doubt that Saillet's "urospectrine" is identical with coproporphyrin Studies in our laboratory in the past two years have revealed entirely similar behaviour The chromogen does not fluoresce in Wood's light, and in the modification of Fikentscher's method that we have hitherto used (Schwartz et al. 1947) it is left behind undetected in the ether We have now determined that the conversion of chromogen to porphyrin is promoted by light, heat, and many dehydrogenators (Watson et al. 1951, Schwartz et al 1950)[1] These relationships are briefly summarised as follows

Coproporphyrin chromogen or precursor
(colourless and non fluorescing)



*Indicates order of procedures

Iodine in very dilute solution has so far proved most efficient (Schwartz et al. 1950) Titrations with iodine have clearly shown that coproporphyrinogen, as formed in vitro by the sodium-amalgam reduction of coproporphyrin, has six hydrogen atoms, of which four are probably added to the four methene bridges and two to the free nitrogens A new method of quantitative determination, devised by Dr Schwartz in this laboratory and described in detail by Watson et al. (1951), uses iodine to convert chromogen to porphyrin, and is not only considerably simpler and more reliable than previous methods but also much more sensitive, requiring only 5 ml. of urine, this advantage being due to the use of a

---

[*] Given in part as a University of London lecture on June 27, 1950 The work was aided by grants from the United States Public Health Service (RG no 345) and from the Medical Research Fund of the Graduate School University of Minnesota

[1] Since this lecture was given an abstract has appeared by D N Raine (*Biochem J* 1950, 47, xiv) in which the natural occurrence of a chromogen of coproporphyrin is discussed, also a method of conversion to porphyrin by the use of quinhydrone Our own experience with quinhydrone indicates that it is not as efficient as iodine

Society of Chiropodists

The annual convention of the society will take place on April 26, 27, and 28, at Friends House, Euston Road, London, N W 1 Sir Henry Cohen will open the convention, and other speakers will include Lord Amulree and Mr T T Stamm

Association of French-speaking Pædiatricians

The association will hold its 13th congress at Algiers from May 7 to 9 Further particulars may be had from the Expansion Scientifique Française, 23, rue du Cherche Midi Paris, VI

International Congress of Gynæcology

To celebrate their jubilee the French Society of Gynæcology, in collaboration with UNESCO, are holding an international congress at the Centre Marcellin Berthelot, 28 bis, Rue St Dominique, Paris, from June 23 to 29 Further information may be had from Dr Maurice Fabre, secretary general, 1, rue Jules Lefebvre, Paris, IXe

South African Minister of Health

Dr Karl Bremer has been appointed South African minister of health and social welfare in succession to the late Dr Stals Dr Bremer obtained his M B degree at Cape Town University in 1935 and his F.R C S in 1938 On his appointment as minister he resigned from the presidency of the South African Medical Council, an office which he had held for many years

C M F /M E F Physicians' Reunion Dinner

This dinner will be held this year in the hall of the Royal College of Physicians of Edinburgh on Saturday, May 12 Any physician who served in these Commands during the war should write to the Edinburgh secretary, Dr R W D Turner, 20, Warriston Crescent, Edinburgh

South Wales Medical Ex-Service Association

This association will hold their annual reunion dinner on Saturday, March 3, at the Park Hotel, Cardiff, at 7 45 P M Colonel D P Holmes will be in the chair Tickets (12*s* 6*d*) may be had from the hon secretary, Mr C W D Lewis, surgical unit, Royal Infirmary, Cardiff

The Minister's Reception

On Friday last Mr Hilary Marquand, the Minister of Health, held a reception at the new office of his Ministry in Savile Row The move from Whitehall, where the Ministry 's present offices will be occupied by the Minister of Local Government and Planning, is taking place gradually over the next few weeks

London Hostel for Tuberculous

At the end of last year the Ministry of Health approved in principle of the London County Council's proposal to provide hostel accommodation for people with tuberculosis who are infectious but are unlikely to benefit by further sanatorium treatment and who have no suitable home of their own (see *Lancet*, 1950, ii, 779) The L C C announce that they are now setting up a hostel of this kind for 35 men in Islington

World Health Organisation

Japan has applied for full membership in W H O The application has been placed on the agenda of the World Health Assembly due to open on May 7 in Geneva According to the W H O constitution, States not belonging to the United Nations can be admitted as members by simple majority vote of the assembly To date, 74 countries have joined W H O and one country, Southern Rhodesia, has been admitted as an associate member

---

Mr C Price Thomas, under the auspices of the British Medical Association and the British Council, is spending two weeks in Yugoslavia lecturing and giving demonstrations of the surgical treatment of tuberculosis He is accompanied by Dr Robert Machray and Mr Peter Jones

The Royal Society for the Prevention of Cruelty to Animals has issued the 7th edition of its booklet on First Aid and Fire Precautions Copies may be obtained, price 6*d* , from the society, 105, Jermyn Street, London, S W 1

CORRIGENDUM : *Potassium Deficiency in Idiopathic Steatorrhœa* —Dr Lubran and Dr McAllen inform us that in the report on the blood chemistry of their patient (*Lancet*, Feb 10, p 321) the figures for sodium should have been 301 mg (130 9 m eq), for calcium 7 6 mg (3 8 m eq), and for phosphorus 3 2 mg (1 8 m eq)

SOME RECENT STUDIES OF PORPHYRIN METABOLISM AND PORPHYRIA*

C J WATSON
M.D, Ph.D Minn, F.A C P
)FESSOR OF MEDICINE UNIVERSITY OF MINNESOTA MEDICAL SCHOOL AND HOSPITAL, MINNEAPOLIS

I HAVE chosen the subject for this lecture with a very l sense of humility, having in mind the many out- nding contributions made by London porphyrin iolars over the last half-century I am the proud ssessor of a reprint from THE LANCET of Sir Archibald rrod's Bradshaw lecture for 1900 on the Urinary gments in their Pathological Aspects This contains emarkable number of interesting observations on what is then mistakenly termed hæmatoporphyrin, now lled coproporphyrin. The more recent studies in this ld by London investigators, notably Rimington arrison, Gray, and Prunty and their associates, have ovided a great stimulus to all who, like myself, are erested in the clinical and fundamental aspects of the rphyrins

CLASSIFICATION

It is perhaps not surprising that the earlier studies of e porphyrins confused the artificial hæmatoporphyrin th those which occur in Nature This difficulty may be cribed at least in large part to the relatively crude ectroscopes available at the turn of the century, ese were too insensitive to detect the slight differences absorption spectra, especially between hæmato- rphyrin and coproporphyrin, whose spectra are almost entical Hans Fischer was the first to put this matter a firm footing, by crystallising the more important of ie naturally occurring porphyrins and clearly establish- g their identity on the basis of various physical criteria 'ischer 1915, 1930, Fischer and Orth 1937) Copro- orphyrin, so called because it was first found in the ces, was noted to be ether soluble, whereas uropor- hyrin, first isolated from the urine, was insoluble in her The most widely represented porphyrin, that of ie hæmoglobin molecule and of other iron porphyrin izymes, was appropriately named protoporphyrin his was also found to be ether soluble, but easily parated from coproporphyrin by being extracted from ther only by more concentrated hydrochloric acid, by xhibiting an insoluble sodium salt, and by chloroform olubility

Fischer (1930) recognised a "dualism" of the por- hyrins in Nature—i e, the existence of two isomeric eries which he believed to be synthesised independently, concept which has been fully borne out by subsequent ork The classification of the porphyrin isomers depends n the four artificial ætioporphyrins prepared by Fischer nd his associates The structural formulæ are given y Fischer and Orth (1937) and Watson and Larson 1947), and it will suffice to recall now that the ætio- porphyrins have only methyl and ethyl groups on the ight positions of the four pyrrol nuclei, the latter being joined by methene (CH) bridges to form the porphyrin ing There are but four possible differing combinations, and hence isomers, of the ætioporphyrins The proto- porphyrin of the hæmoglobin molecule corresponds in configuration to ætioporphyrin III, and, as we shall note in a moment, there is also a type III coproporphyrin which is probably of considerable importance in hæmo- globin metabolism Coproporphyrin I differs only by reversal of the side groups on pyrrol nucleus IV Th[illegible] difference, nevertheless, is such that type I could not [illegible] derived from type III without complete disruption [illegible] resynthesis, hence the formation of type I is genera[illegible] regarded as an independent synthesis Types II and [illegible] have not so far been encountered in Nature, either [illegible] coproporphyrin or any other form of porphyrin. Suffic[illegible] data have now accumulated to indicate the unlikelihood that either II or IV will be found, and it is now reasonabl[illegible] clear that the enzyme systems necessary to porp[illegible] formation relate only to types I and III Uroporph[illegible] has four acetic acid groups instead of the four m[illegible] groups of coproporphyrin, since it also has t[illegible] propionic acid groups it is an octacarboxyl po[illegible] whereas the coproporphyrins are tetracarboxyl [illegible] question of occurrence of a uroporphyrin III w[illegible] considered subsequently

URINARY EXCRETION

The study of the urinary excretion of copro[illegible] has been based mainly on fluorimetry, bec[illegible] porphyrins generally exhibit an intense red f[illegible] when exposed to light of about 4000 Å Variou[illegible] tions of Fikentscher s (1932) method have bee[illegible] In all of them it is assumed that any porphyrin [illegible] as chromogen or leuco compound is converte[illegible] phyrin during extraction and purification [illegible] however we have "rediscovered" a fac[illegible] undoubtedly known to Saillet (1896), alt[illegible] minology and description were somewha[illegible] recognised that his "urospectrine" [illegible] porphyrine normal" occurred in part [illegible] colourless chromogen which was not [illegible] from ether or from ethyl acetate by [illegible] There appears to be little doubt that [illegible] trine" is identical with coproporphyrin [illegible] laboratory in the past two years ha[illegible] similar behaviour The chromogen [illegible] Wood's light, and in the modification [illegible] method that we have hitherto used [illegible] it is left behind undetected in the [illegible] determined that the conversion of [illegible] is promoted by light, heat, and [illegible] (Watson et al 1951, Schwartz [illegible] relationships are briefly su[illegible]

CLASSIFICATION AND MAIN FEATURES OF PORPHYRIA

Type and incidence	Clinical	Chemical
1 PHOTOSENSITIVE (congenital) Rare	Somewhat more common in males Onset early in life either prenatal or postnatal Hydroa æstivale eventual scarring and mutilation of exposed skin erythrodontia Splenomegaly and hæmolytic anæmia not infrequently splenectomy may relieve and cause porphyria to become latent with disappearance of photosensitivity	Absence of Ehrlich reacting porphobilinogen in urine Presence of large amounts of uroporphyrin and coproporphyrin I both excreted in part as colourless Ehrlich negative chromogens (in urine urocopro in fæces vice versa) Slight or negative zinc complex formation by these porphyrins Uroporphyrin I methyl ester M.P 284°C
2 INTERMITTENT ACUTE (acute or toxic ') Relatively common	Somewhat more common in females Abdominal pain of various types Peripheral neuropathy with pain in extremities Varying neuropsychiatric disturbances weakness paralyses hysterical behaviour or outspoken psychoses Pigmentation of skin in some cases	Porphobilinogen usually present in urine at least during attacks (Ehrlich $CHCl_3$ insoluble aldehyde) Non Ehrlich reacting chromogen $\downarrow -H_2$ Waldenström uro type porphyrin (zinc complex) methyl ester M P 258–260 C Porphobilinogen (colourless) ? $\rightarrow$ Waldenström Porphobilinogen (colourless) $\downarrow$ Porphobilin (dark brown) non porphyrin probable dipyrryl methene or polymer thereof coproporphyrin III usually excessive
3 MIXED (' chronic) Relatively uncommon	Differing sex incidence not clearly defined probably somewhat more common in males Late appearance of photosensitivity (so called cutanea tardive type) Relatively benign course Liver disease or functional impairment frequent Attacks of abdominal pain neuropsychiatric disturbances infrequent	Porphobilinogen inconstant. Varying appearance of Waldenström uro type porphyrin or uroporphyrin I with various mixtures of coproporphyrins I and III

than with the concept of Lemberg and Legge (1949) that one member of a pair of specific dipyrryl methene precursors capable of condensing to form coproporphyrin III is normally converted to a dipyrryl methene precursor of protoporphyrin by decarboxylation Among other features which this theory was believed to explain is the very small amount of coproporphyrin III normally encountered in the urine and fæces, but it does not harmonise as well with the finding of coproporphyrin in the bone marrow and erythrocytes and the increases observed when erythropoiesis is stimulated even in a relatively normal way, as after blood loss or reduction of oxygen tension (Schmid et al 1950) Perhaps even more important is the lack of any increase of coproporphyrin III in the urine in posthæmorrhagic or hæmolytic anæmias, since, if it were merely a side product of hæmoglobin synthesis, significant increases in these circumstances would be anticipated, but they have not been observed (Watson and Larson 1947, Dobriner and Rhoads 1940) The recent hypothesis of porphyrin biosynthesis proposed by Neuberger et al (1950) looks on coproporphyrin III as intermediary in the formation of protoporphyrin, and is thus in better agreement with the various findings just referred to which relate to this area of the biosynthesis As is noted below, the rôle of uroporphyrin is still very difficult to assess, although Neuberger et al believe that uroporphyrin III is a normal precursor of coproporphyrin and protoporphyrin

PORPHYRIA

We may turn now to the problem of porphyria which, as Garrod (1923) recognised, is a special situation, an inborn error of metabolism " A classification of porphyria is submitted in the accompanying table, together with the outstanding clinical and chemical features

As noted in the table, the " cutanea tarda " form, which in some instances presents nothing more than photosensitive manifestations, is nevertheless classified with the mixed type Probably this form differs essentially from the infantile or so called congenital photosensitive variety As Brunsting et al (1950) have emphasised, these patients commonly present (1) evidence of liver disease, (2) a violaceous hue of the exposed skin with or without pigmentation and/or hypertrichosis, and (3) bullæ caused by heat and trauma as well as light From a fundamental standpoint it is perhaps even more important that the bone marrow in such instances may not contain any increased amount of porphyrin, whereas the liver, examined at about the same time, contains large amounts of porphyrins, in contradistinction to the pure photosensitive disease in which coproporphyrin and uroporphyrin are formed in the bone marrow to a striking degree (Aldrich et al 1950) Further comparative studies of this type, which are now in progress, may well provide a much more basic classification of porphyria [3]

A fact which is noted in the table and has been recognised but recently (Schwartz et al 1950) is the occurrence of a chromogen, other than porphobilinogen, both for uroporphyrin I and the Waldenström uro type porphyrin This is readily demonstrated by extraction of the urine with ethyl acetate after acidification with acetic acid Porphobilinogen is not extracted, but one regularly finds a chromogen in the ethyl acetate which is not removed by 1 5 *N* HCl until the solution has first been washed with 0 05% iodine solution This converts chromogen to porphyrin, after which it is readily extracted with HCl This finding makes it uncertain whether the Ehrlich reacting porphobilinogen is actually a porphyrin precursor as has been believed (Waldenstrom and Vahlquist 1939), or its apparent transition to a uro type porphyrin is simply a matter of being accompanied by an Ehrlich negative porphyrinogen The careful electrophoretic purification of Waldenstrom and Vahlquist (1939) supported the former belief, but porphobilinogen has not been crystallised , and, until it can be studied as a chemical entity, this question must remain unanswered Meanwhile the porphobilinogen aldehyde test, depending on the chloroform insolubility of the resulting Ehrlich compound (Watson and Schwartz 1941), serves as the simplest method in the diagnosis of the intermittent acute type of porphyria Present experience indicates that the reaction, though not wholly pathognomonic characterises the intermittent acute form of porphyria was believed by Waldenstrom (1937), Mertens (1937), and Chandler et al (1939) to represent uroporphyrin III Studies in this laboratory have shown, however, that it is a curious mixture or molecular complex of uroporphyrin I with a type III porphyrin which probably has less than eight carboxyl groups Prunty (1946), McSwiney et al (1950), and Gray (personal communication) have confirmed the finding of uroporphyrin I as an important constituent of the Waldenstrom porphyrin Recent methoxy determinations have borne out our earlier finding of a heptamethyl ester (melting point 208°C) The nature of the combination of this porphyrin with uroporphyrin I in the Waldenstrom porphyrin is not clear, but it may be noted that in some cases, and even at certain times in the same case, it has been impossible to separate the uroporphyrin I from the admixed type III porphyrin on the $CaCO_3$ column (So far a separation by paper chromatography has not been reported) This inseparable behaviour has been referred to as the type-B Waldenstrom porphyrin in contradistinction to type A, in which uroporphyrin I is readily separated from the 208 or heptacarboxyl porphyrin A binding factor may operate to a variable extent in conditioning these differences Gibson and Harrison (1950) have observed that a porphyria urine which initially yielded uroporphyrin I (ester melting point 282–5°C) yielded seven times as much porphyrin after being boiled, but now the ester melting point was lowered to 264–5°C This behaved as a type B Waldenstrom porphyrin, and a 208 porphyrin was not observed Additional studies of this type are needed with urine from various cases of porphyria Recently the administration of N^{15} tagged uroporphyrin I (methyl ester melting point 284°C) in a case of intermittent acute porphyria has yielded significant data The patient was excreting large amounts of porphobilinogen and Waldenstrom porphyrin The latter was separable on the Tswett column into uroporphyrin I and the 208 or heptacarboxyl porphyrin The uroporphyrin I which was administered had been crystallised from the urine of a girl, aged 5 years, with photosensitive porphyria with splenomegaly and hæmolytic anæmia (Grinstein et al 1949) N^{15} glycine had been fed to this girl a few days earlier, as a result of which the uroporphyrin I contained 3 2 atom per cent excess of N^{15} (Grinstein et al 1949, 1950a) 7 mg of this material was given intravenously in divided doses over three days The uro type porphyrin isolated from the recipient of the uro I during this period had an ester melting point of 260–4°C, but it behaved as an entity on the Tswett column The crystals obtained from urine and fæces contained 0 032 and 0 045 atom per cent excess of N^{15} respectively, whereas the value for the urine and fæces coproporphyrin isolated simultaneously was 0 00 atom per cent excess Thus it was clear that at least the N^{15}, and quite probably the tagged uroporphyrin I in toto, had become incorporated to some extent in the Waldenstrom porphyrin which was isolated It was not clear, however, whether the administered porphyrin had occasioned the behaviour as an entity, or whether this was a pure coincidence As already mentioned, such variations in behaviour have been observed in other instances It was thought significant that the coproporphyrin I isolated after the administration of the N^{15} uroporphyrin did not contain any excess of N^{15} Though this finding does not weigh too heavily against a uro copro transition it clearly does not support it Since this patient could make considerable excesses of both coproporphyrin isomers, it seems that more biological than the carboxylation of four to four acetic acid groups, as would be necessar conversion of coproporphyrin to uroporphyrin however, no decisive evidence of either sequence h described Of the three studies so far reported ı porphyria has been studied with glycine contain those of Grinstein et al (1949, 1950a) and Gr Neuberger (1949) have revealed an earlier and peak concentration of N^{15} in the coproporphyrin the uroporphyrin This relates to the urine por only, the variable lag in excretion in the fæces comparison of urinary and fæcal porphyrin N^{15} difficult if not impossible In the third of these (London et al 1950) the peak concentration developed earlier in the uroporphyrin than in the porphyrin, but the latter value depended on th rather than the urinary coproporphyrin Even the data are quite comparable, as in the first two referred to, the possibility must be considere uroporphyrin has a later and lesser peak concen of N^{15} owing to a larger "pool" or a greater and slower release of uroporphyrin than of co phyrin This consideration prevents conclusions possibility must also be borne in mind that uropor and coproporphyrin are only related on the b common precursors, neither being the parent sub of the other This concept is given prominent pl Lemberg and Legge (1949)

---

[3] Since this was written Dr Schmid has studied liver biopsy material from additional cases of the ' mixed " type This study revealed large amounts of porphyrin in the liver, with slight or no increase in the bone marrow The term ' porphyria hepatica ' is tentatively considered most suitable for this group, while, conversely, " porphyria erythropoietica " seems to designate most accurately the fundamental disturbance in the pure photosensitive or congenital form

CONCLUSION

In closing, it is desirable to refer again to the l thesis of the porphyrins recently proposed by Neu et al (1950) This postulates an initial synth uroporphyrin III, hence the identification o substance seems to be a primary requisite to the of their hypothesis This porphyrin might be a p logical precursor but not demonstrable owing to of reaction One might anticipate, however, that it be found in certain conditions, such as lead pois which are characterised by excessive type III cop phyrins, since there is much reason to believe that excesses are due to an enzymatic disturbance ı synthesis of hæmoglobin

Finally, it is a pleasure to acknowledge that in desc work from our laboratory I have simply been the spok for a number of my associates, in particular Dr S Schwartz, Dr Moises Grinstein, Dr Robert Aldrich, Dr Lowry, Dr Rudi Schmid, Miss V E Hawkinson, Miss Bossenmaier, and Mrs Rita Hughes

SENSIBILITY OF THE RECTUM AND COLON

ITS RÔLE IN THE MECHANISM OF ANAL CONTINENCE

J C GOLIGHER

It is known from the work of Lennander (1901), Hurst (1911), and others that, with the exception of the anal canal, the gut is largely insensitive to stimuli capable of producing pain or other sensation when applied to a cutaneous surface It is, however, sensitive to distension by an experimental balloon introduced through the mouth, the anus, or a colostomy, though it is not clear whether it is the stretching or reflex contraction of the gut wall, or the distortion of the mesentery that produces the pain The same doubt exists as to the mechanism of the pain in ordinary intestinal colic According to Hurst (1911), the sensation of fullness in the rectum that constitutes the normal call to defæcation is also due to distension, and is caused by the sudden entry of fæces into this segment of the bowel

In this paper we describe some observations on the sensations produced by balloon distension of the rectum and distal colon in normal subjects and in patients who have had the nerve supply to the bowel interrupted or varying portions of the rectum removed. In the latter group we try to correlate our findings with the functional result obtained The balloon, mounted on the end of a narrow graduated rubber tube, was inserted into the rectum and the lower part of the sigmoid colon through a sigmoidoscope , the instrument was then withdrawn over the tube, and the tube was connected to a pair of bellows and a mercury manometer The balloon was inflated at the highest level reached by the sigmoidoscope —usually 25 cm , sometimes only 20 cm, from the anus —and the minimum pressure required to produce sensation and the patient's description of the sensation were recorded It was then deflated and the process repeated at 5 cm intervals right down to the anus In the few cases where the balloon was introduced through a colostomy, the same technique of insertion with the aid of a sigmoidoscope was employed Distension was then performed at measured distances from the actual opening

It will be apparent that the recordings made by this apparatus do not accurately represent the tension exerted on the gut wall, because some of the pressure is engaged in overcoming the resistance of the balloon itself Preliminary tests showed that inflation of the balloon to a size sufficient to distend the colon at all—diameter about 3 cm —required a pressure of approximately 20 mm Hg, but that further dilatation to a diameter of 9 cm required a rise of pressure of only about 5 mm Hg Practically all the pressures recorded with the balloon in situ lay between 60 and 150 mm Hg, so the differences between them may be accepted as reflecting with reasonable accuracy the variations in the sensibility of the bowel

FINDINGS IN NORMAL SUBJECTS

The following account is based on the results obtained in forty normal people

Colonic Sensation

Distension of the sigmoid colon, and occasionally the upper part of the rectum, caused a sensation in the lower abdomen, either in the midline suprapubically or in the left iliac fossa Usually considerable pressure was required to elicit this sensation (average 80 mm Hg , extremes 40 and 140 mm Hg), and there was a lag of 2 or 3 seconds between the inflation of the balloon and its appreciation by the patient If no further inflation was carried out the pressure gradually fell, presumably owing to relaxation of the intestinal wall, and this fall was associated with a waning of sensation, which eventually disappeared in 30 or 40 seconds unless the threshold had been much exceeded in the first instance The sensation was sometimes described by the patient as being like " wind " in the bowel , at other times as a definite pain, rather like a colic but constant and not spasmodic On increasing the pressure the sensation always became painful

Rectal Sensation

Distension of the rectum proper caused a characteristic sensation referred to the rectum itself or the sacral region The pressure needed to elicit this sensation was usually lower—sometimes considerably lower—than that required to produce colonic sensation in the same individual (average 62 mm Hg , extremes 25 and 130 mm Hg) The latent interval between the inflation of the balloon and its perception by the patient seemed to be slightly shorter than with the colon It was noted that the pressure threshold for sensation was slightly lower when the balloon was distended rapidly instead of slowly As with the colon, once the sensation had been established, and in the absence of further distension, the pressure gradually sank and the sensation steadily diminished in intensity over a period of $^{1}/_{2}$–1 minute or more, perhaps finally disappearing altogether Like Gaston (1948a), we found that the sensibility of the rectum increased as the anus was approached, for the average pressures needed to produce sensation at 20, 15, 10 and 5 cm from the anal orifice were 67, 63, 61 and 56 mm Hg respectively

The patients' description of the sensation varied A few stated that they had never experienced anything quite comparable before, but the majority likened it to that of wind or motion in the rectum requiring evacuation In more than half the cases it was found that lesser

degrees of pressure caused a sensation of flatus in the rectum; when the pressure was increased by 10 or 20 mm. Hg, however, the sensation became more urgent and the patients now stated that they felt they wanted to pass a motion. In some cases the distinction between flatus and fæces did not seem to depend on differences of pressure, the patients feeling one or other throughout or being unable to state with confidence which they thought was present in the rectum.

When the balloon was inflated in the anal canal an entirely different sensation from that created in the rectum proper was produced. Instead of having a desire to defæcate or pass wind, the patient now felt that the motion was actually escaping from the anus, and indeed unless special care was taken to maintain the balloon in position it was automatically evacuated.

Localisation of Colonic and Rectal Types of Sensation

The line of demarcation between the zones in which rectal and colonic sensation could be elicited did not always correspond accurately to the anatomical division into rectum and colon. The rectosigmoid junction is usually taken to lie between 12 and 15 cm. from the anus. In our 40 subjects the boundary between the zones of rectal and colonic sensation lay more than 25 cm. from the anus in five, between 25 and 20 cm. away in nine, between 20 and 15 cm. in ten, and between 15 and 10 cm. in four. In twelve cases there was a zone where colonic and rectal sensation overlapped for 10 to 15 cm. between the 25 cm. and 10 cm. levels.

Reflex Contraction of the External Sphincter Ani during Balloon Distension

Garry (1933) showed that in animals distension of the rectum with a balloon evokes a reflex contraction of the external sphincter, and this has also been elicited by Gaston (1948a) in human beings. The behaviour of the external anal sphincter was therefore noted during our investigations. No elaborate recording apparatus was employed; the tip of the index finger was simply placed at the anal orifice in contact with the subcutaneous external sphincter. Even slight contraction of the muscle could be readily appreciated. It was found that balloon distension producing rectal sensation invariably caused contraction of the external sphincter. Occasionally, indeed, the muscle contraction seemed to precede appreciation of sensation by a second or so. Distension of the segments of bowel causing colonic sensation was not accompanied by contraction of the sphincter.

FINDINGS AFTER INTERRUPTION OF NERVE SUPPLY

The nerve supply to the rectum and sigmoid colon is derived from the sympathetic and parasympathetic nervous systems, and from the inferior hæmorrhoidal branches of the pudendal nerves. According to Gask and Ross (1937), the *sympathetic* fibres originate in the lower 6 thoracic and upper 2 lumbar segments of the spinal cord and pass via the thoracic and lumbar splanchnic nerves to join the aortic plexus. Some then proceed along the presacral nerve; this divides into right and left branches which combine with the parasympathetic branches from the 2nd and 3rd sacral segments to form the pelvic plexuses, from which in turn branches are distributed to the rectum and other pelvic organs. Other fibres pass from the aortic plexus to the inferior mesenteric plexus, which accompanies the inferior mesenteric artery and is distributed along the branches of that vessel to the colon and rectum.

The *parasympathetic* supply comes from the 2nd, 3rd, and 4th sacral segments of the cord (*Gray's Anatomy* 1949). Some fibres proceed directly to the pelvic plexuses and are distributed from these; others, as Telford and Stopford (1934) have shown, form a trunk which passes upwards to join the inferior mesenteric plexus and are conveyed in its branches to the left half of the colon and the rectum. It is not believed that the vagi send fibres farther distally than the splenic flexure of the colon—if indeed as far as this.

The *inferior hæmorrhoidal* branches of the pudendal nerves (S2, 3, and 4) cross the ischiorectal fossæ to supply the external sphincter ani; they also contain sensory fibres from the skin, and possibly from the mucosa of the anal canal and lower rectum (*Gray's Anatomy* 1949).

Afferent nerve impulses from the rectum and distal colon must be transmitted along one or more of these routes. To determine the relative importance in this respect of the three pathways, experiments were carried out in which each was blocked in turn and the effect on the sensibility of the rectum and colon was observed.

Inferior Hæmorrhoidal Block

In six patients requiring surgical treatment for rectal conditions, such as anal warts or external hæmorrhoids, which can be dealt with very satisfactorily under local anæsthesia, the opportunity was taken to block the inferior hæmorrhoidal nerves. Anæsthesia was achieved by the injection through a puncture 1 in. behind the anus of 20 ml. of 2% procaine on either side of the anal canal. Complete paralysis of the external sphincter indicated that conduction in the inferior hæmorrhoidal nerves had been successfully interrupted. Balloon distension of the rectum and colon was carried out before and after the injection. The only change noted after blocking the inferior hæmorrhoidal nerves was a very slight lowering of the pressure threshold for sensation in both rectum and colon.

Parasympathetic Block

The parasympathetic outflow from S2 and 3 can be interrupted by a low spinal anæsthetic such as is commonly used for minor rectal operations, &c. 0·8 ml. of 1/2000 heavy 'Nupercaine' solution is injected into the subarachnoid space between the 3rd and 4th lumbar spinous processes, the patient being kept sitting up for four minutes afterwards. Anæsthesia develops up to the 2nd or 1st sacral nerve segments, which suffices to block the sacral parasympathetic nerves (and also incidentally the pudendal nerves and their inferior hæmorrhoidal branches) but does not affect the sympathetic supply to the colon and rectum.

Six cases were investigated by balloon distension before and after induction of low spinal anæsthesia. It was found that colonic sensation was quite unaffected by the anæsthetic but that rectal sensation was completely abolished. The most vigorous distension of the rectum after the injection caused no sensation whatsoever, though in two cases the colon and rectum were stimulated thereby to expel fæces and flatus, the patients being quite unaware of this till the flatus was heard escaping from the anus.

Sympathetic Block

In the surgical treatment of essential hypertension the extensive sympathectomy advocated by Grimson—division of the sympathetic outflow from T3 to L3 on both sides—is now frequently employed. This operation also deprives the entire colon and rectum of their sympathetic supply. Six cases of hypertension which had had a bilateral denervation of this type were examined by balloon distension of the rectum and colon. Unfortunately, in five of the patients it was found impossible, for technical reasons, to insert the sigmoidoscope further than 15 cm.; balloon distension up to this level gave a rectal sensation of flatus or fæces. In the sixth patient the sigmoidoscope was passed to 25 cm.; balloon distension as far as this point produced a rectal sensation but no abdominal pain. It should be added that all six patients had normal rectal function.

FINDINGS AFTER PARTIAL OR COMPLETE EXCISION OF RECTUM

Complete Abdominoperineal Excision with Terminal Iliac Colostomy

In six patients who had had this operation some months or years previously, balloon distension of the segment of colon leading to the colostomy was carried out, only a sensation of pain referable to the hypogastric or umbilical region was elicited. Even when the balloon was withdrawn so as to lie immediately adjacent to the anterior abdominal wall there was never any sense of fullness in the vicinity of the colostomy, and this was in keeping with the experience of these patients that the escape of fæces or flatus from their colostomies was never preceded by any warning sensation.

Partial Excision with Preservation of Anal Sphincters

Abdomino anal excision of "pull through" type (Bacon 1945, Babcock 1947).—In this operation the lower sigmoid colon, all the rectum proper, and the anal mucosa as far as the mucocutaneous junction are removed, the stump of colon is pulled down through the anal orifice, and the anal sphincter which has been divided in the midline posteriorly, is sutured around it. Eventually the projecting portion of bowel sloughs off or is removed by diathermy or snare, leaving the state of affairs shown in fig. 1.

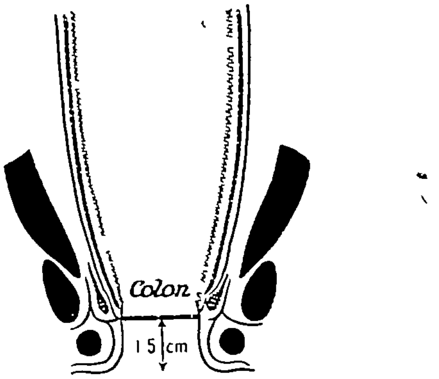

Fig. 1—Diagram showing the state of affairs after the Bacon Babcock operation when the excess of bowel projecting through the anus has been removed.

Four patients who had been subjected to this procedure were examined. The anastomosis between the colon and the anal canal was situated 0·5–1·5 cm from the anal orifice; two cases had a fairly tight fibrous stenosis at this level. In all cases the tone of the external sphincter was very poor and its contractile power slight or non existent. The puborectalis muscle showed better tone and could contract—in two cases quite strongly. In view of the atonic, often patulous, condition of the anus it was not surprising that all four patients were incontinent; careful interrogation disclosed further that they were devoid of ordinary rectal sensation. Three stated that they sometimes had a vague sense of discomfort in the perineal or sacral region immediately before the expulsion of fæces or flatus. More often a "windy" sensation in the lower abdomen due to active colonic peristalsis indicated that a motion or escape of flatus was imminent but they had come to dispense with sensation as a guide in these matters and had endeavoured, by attention to diet, to establish a routine like that followed by colostomy cases. They found it necessary, however, to wear a perineal pad constantly during the day to protect their clothing from soiling, and a bout of diarrhœa confined them to the house. It was difficult to see how such a patient was any better off than one with an abdominal colostomy.

Balloon distension of the colon from 15 cm down to the suture line elicited an abdominal sensation in all four cases; when the pressure was increased to 180 mm Hg a very vague rectal sensation was also experienced in three subjects.

Abdomino anal excision of invagination type (Maunsell 1892, Weir 1901).—In this procedure the lower part of the sigmoid colon and the greater part of the rectum are excised through the abdomen, the subsequent anastomosis between the colon and lower fringe of rectum being accomplished by everting the anorectal stump through the anus and drawing the colon down through it so that their cut edges can be approximated by suture outside the anus; afterwards the suture line is replaced within the pelvis. By this technique the anal sphincters and lower anorectum are retained undamaged (see fig. 2).

Nine such cases were considered. The bowel suture line was usually situated about 6 or 7 cm from the anal orifice. The tone and contractile power of the sphincters and puborectales were normal in all cases. Rectal function was excellent in all but two patients, who found that they were unable to control flatus or liquid fæces. One of these incontinent patients was able to tell when wind or motion was present in the bowel, but in the other rectal sensibility seemed to be grossly impaired.

Balloon distension with the balloon lying just above the anorectal ring, and therefore partly or entirely below the suture line, always produced a sensation of rectal fullness. With the balloon above the suture line an abdominal sensation was invariably elicited, but in six of the nine cases this was accompanied by a rectal sensation as well.

Abdominal or anterior resection.—Here the resection of the cancerous segment per abdomen is followed by a sutured anastomosis between the colon and the rectal stump from above, a substantial portion of rectum usually being retained, as in fig. 3.

Examination of ten patients subjected to this operation yielded the following information: the suture lines lay between 7·5 and 13 cm—usually 9 or 10 cm—from the anal orifice. The tone and contractility of the sphincters and puborectales were invariably excellent, and the functional result could be classed as perfect in all cases. Balloon distension below the suture line caused a purely rectal sensation; above the suture line it always caused an abdominal sensation, but in two cases a rectal sensation as well.

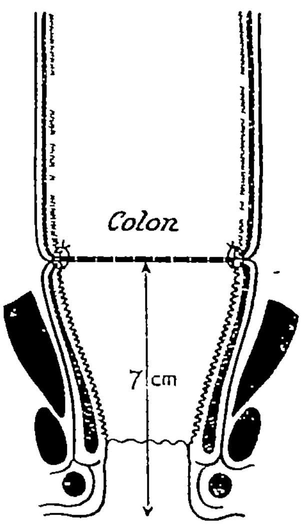

Fig. 2—Diagram showing the result of abdomino-anal excision of invagination type with suture line replaced through the anus.

DISCUSSION

Distinction between Colonic and Rectal Sensation

This investigation confirms in the main Hurst's (1911) contention that balloon distension of the colon in normal subjects produces a purely abdominal sensation of "flatulent" discomfort or pain, whereas rectal distension causes a feeling of fullness in the rectum interpreted by the patient as a desire to pass wind or motion. It shows, however, that the distribution of the two types of sensation in the bowel does not always coincide accurately with the anatomical division into rectum and colon It also demonstrates that the rectum is more sensitive and discriminating than the colon this is indicated by the lower pressure at which sensation can be elicited in the former, and by the ability of the rectum to distinguish between flatus and fæces, which the colon cannot do Some evidence is presented which suggests that flatus normally produces a slightly lower degree of intrarectal tension than does fæces, and that the rectum is able to appreciate these minor differences of pressure but it may well be that the distinction depends, at least in part, on the recognition by the rectum of some other physical or chemical quality in its contents, not considered in this study

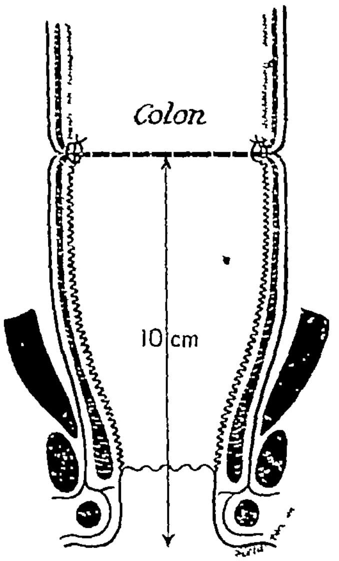

Fig 3—Diagram showing state of affairs after abdominal resection with intrapelvic anastomosis

This difference in the sensitivity of the rectum and colon is also seen under ordinary functional conditions During normal peristalsis considerable tension is presumably generated in the colon, but this usually produces no sensation, apart from occasional slight abdominal discomfort It is only when peristalsis becomes greatly exaggerated, as with drastic purgation, that actual pain is experienced The rectum, by contrast, is able to detect quite small quantities of flatus, and to distinguish them reliably from fæces, except perhaps during an attack of diarrhœa

Site of Origin of the Stimulus Producing Sensation in the Colon and Rectum

It has never been satisfactorily established where precisely the nerve endings are situated which transmit sensations from the bowel The matter cannot be decided anatomically because there are no recognisable sensory nerve endings in the bowel wall Presumably, therefore, afferent nerve impulses originate in free unencapsulated nerve terminals, which unfortunately cannot be distinguished from the nerve endings of intramural plexuses Hurst (1911) claimed, without producing any real evidence, that sensation was experienced in the muscularis, while Garry (1933) tried to show by experiments, in which he painted the rectal mucosa with a cocaine solution, that afferent impulses originated in the mucous membrane However, the anæsthetic solution might conceivably have been absorbed into the muscle coat as well, as Garry admits, and his work cannot be regarded as conclusive

It has been suggested by Lennander (1901), and more recently by Lewis and Kellgren (1939), that bowel pain does not originate in the gut wall at all, but is due to stretching of the sensitive mesentery We refer to this possibility because of our observation—which incidentally conflicts with the findings of Hurst (1911) and Gaston (1948b)—that stumps of colon brought down into the pelvis to restore continuity after sphincter saving resections of the rectum often acquire an imperfect sort of rectal sensation The fact that patients with an abdominal colostomy never develop a rectal type of sensation in the piece of colon leading to the colostomy suggests that the location of the stump in the pelvis is in some way responsible It is possible that pressure on surrounding parts is a factor in the production of rectal sensation in normal subjects, but it cannot be the only factor since the rectal sensation elicited in these colon stumps is much less delicate and discriminating than normal rectal sensation and requires a higher pressure to elicit it It also seems to be of little value to the patient as a substitute for the sensory function of the normal rectum

Nerve Pathways

Bentley and Smithwick (1940) showed that the pain resulting from balloon distension of the small gut was conveyed by the sympathetic system and was not felt after bilateral resection of the splanchnic nerves and thoracic sympathetic chains Ray and Neill (1947) demonstrated that colonic pain followed the same route and could be blocked by a similar operation if the upper 2 lumbar sympathetic ganglia on both sides were removed as well We had hoped to make some observations on colonic sensation in patients subjected to Grimson's extensive sympathectomy for hypertension but were prevented by technical difficulties from so doing

The pathway for the sensation of rectal fullness has not hitherto been known for certain Our investigations have established that neither the sympathetic system nor the inferior hæmorrhoidal and pudendal nerves play any part in this sensation, which is transmitted solely by the parasympathetic fibres connecting the rectum to the 2nd and 3rd sacral segments

Importance of Rectal Sensibility in the Maintenance of Anal Continence

The lower end of the rectum is embraced by three muscles—the internal and external anal sphincters and the puborectales, which, according to Milligan and Morgan (1934), may also act as a sphincter The internal sphincter is an involuntary muscle, and it has been established by Garry (1933), Denny Brown and Robertson (1935), and Gaston (1948a) that when the rectum is distended this sphincter, far from contracting to resist the raised pressure, undergoes reflex relaxation to facilitate defæcation For these reasons we find it difficult to see what part the internal sphincter can play in controlling the escape of fæces and flatus in accordance with the conventions of civilised life

Anal continence must in our view depend on the action of the external anal sphincter and the puborectales These are voluntary muscles capable of vigorous active contraction They rapidly tire, however, and can maintain this contraction for only a few minutes, as Gaston (1948a) has shown very clearly in the case of the external sphincter In the ordinary way, therefore, they exhibit only moderate resting tone, but when the pressure in the rectum rises suddenly owing to the entrance of flatus or fæces their tone is instantly reinforced, and maintained at this heightened level for a short period, to give the rectal wall time to relax and accommodate the new contents at lower pressure

There has been some dispute as to whether the sphincter contraction in response to rectal distension is purely reflex or whether it involves cortical participation and voluntary effort Gaston (1948a) showed that contraction did not follow balloon distension of the rectum in a patient with a complete lesion of the cord at the level of the 8th thoracic vertebra, it is not, therefore, a spinal cord reflex The same worker, however, claims to have elicited external sphincter contraction by rectal distension in a patient who was asleep, and who had no subsequent memory of a desire to defæcate, which suggests that contact between the sensory and motor sides of the arc can be effected at a subcortical level It will be recalled that, in our investigations, reflex contraction of the external sphincter occasionally seemed to precede by an instant or so conscious appreciation of fullness We have also observed during fistula tions that, when the anæsthesia is sufficiently light, lation of the lower rectum regularly evokes contrac- f both the external sphincter and the puborectales, h the patient is of course still unconscious There e little doubt, therefore, that the initial contraction e sphincter apparatus in response to a rise of intra- l tension is entirely reflex, but this is almost immedi- supplemented by a voluntary contraction as the l sensation reaches consciousness Further, the fine rentiation between fæces and flatus and the subse t decision as to whether sphincter contraction should aintained or relaxed—indispensable components of mechanism of continence—are entirely conscious esses We therefore regard the exercise of anal nence as an essentially conscious activity

nal incontinence may obviously be produced by ry to the motor mechanism, as by injudicious division he anal musculature during fistula operations It is haps not sufficiently widely recognised, however, that may equally certainly result from damage to the sory apparatus even though the muscles may be intact capable of strong voluntary contraction This may pen in sphincter saving excisions of the rectum, ere a scrupulous preservation of the external sphincter scle, the levatores ani, and the motor nerves may none less be followed by a poor functional result This is cause the rectum, with its essential sensory nerve- dings, has been largely or entirely sacrificed the nsequence is that the patient receives inadequate rning of a sudden accumulation of flatus or fæces d so cannot contract his sphincters in time Our amination of patients who had undergone sphincter ving resections of the rectum showed that, though a gue rectal sense was not infrequently developed in the wer part of the colon anastomosed to the rectal stump r anus, this did not seem to be of much practical value the patient, the quality of the functional result was ill dependent on the amount of anorectum preserved elow With an anorectal stump of not less than 8–10 cm, easured from the anal orifice, function was invariably ood a stump of 6–7 cm usually gave good function, hough sometimes rectal sensibility and control were nadequate especially for flatus or liquid fæces Finally patients in whom the whole rectum proper and the anal mucosa as far as the mucocutaneous junction had been excised had no useful rectal sensation or control and would pass flatus or fæces quite unconsciously It is only fair to mention that in these latter cases the external sphinc ter had invariably been divided and resutured round the projecting colon and was found to be in an atonic weak condition, which undoubtedly contributed to the inade quacy of anal control, but it should not have affected sensation

Another way in which "sensory incontinence" may be produced at operation is by damage to the parasym- pathetic and associated afferent nerves from the rectum, Considering the extensive mobilisation of the rectum with division of the lateral ligaments, that is so frequently necessary in resection operations, it might be expected that the remaining rectal stump would often be completely deprived of its sensory nerve supply It was surprising therefore to find that in our resection cases the rectal stump was always sensitive to balloon distension, and poor functional results could not be attributed to denervation of this structure However, the following case record shows that incontinence may result from interference with the sensory nerves of the rectum

A woman of 55 complained of prolapse of rectum at defæcation and on exertion during the day for 10 years She was unable to control flatus or fæces when bowel was extruded but fully continent when prolapse was reduced She had complete rectal prolapse projecting 2 in. beyond anus on straining Sphincter tone fair contractile power good, normal tone and contractile power in puborectalis

On Jan. 6, 1949, combined Roscoe Graham and Moschowitz type of abdominal repair performed under spinal and general anæsthesia Abdomen opened by left paramedian incision, peritoneum divided on either side of the rectum and across the pouch of Douglas rectum mobilised behind and in front, and lateral ligaments completely divided on either side By further dissection, levator ani muscles clearly defined on each side, the puborectales being especially well seen forming sling at anorectal junction. Contiguous edges of these muscles approximated with 4 floss-silk sutures in rectovaginal space, pouch of Douglas obliterated by purse string sutures of fine silk, and finally fundus of uterus fixed to anterior abdominal wall just above pubes by 2 silk sutures Abdomen closed in layers

Patient made good recovery and postoperative examination showed strong pelvic floor, well marked anorectal ring vigorous anal sphincter, and no further rectal prolapse Unfortunately, after operation patient had no control over wind or motion Flatus passed quite unconsciously and involuntarily Unless she was given daily washout to regulate bowel action motion would likewise escape and soil bed linen. Balloon distension was carried out on Feb 2, 1949 and showed that rectum was completely anæsthetic up to 15 cm. Owing to the narrowing produced by operation, it was impossible to pass sigmoidoscope beyond this point to test colonic sensation

Twelve months after operation there is still no sensation of wind or motion in the rectum, and she is virtually incon tinent. Copes with disability by enemata, by frequent defæca- tion and by straining to empty rectum without waiting for large fæcal accumulation to occur Fortunately never has much intestinal flatus Is completely incapacitated by an attack of diarrhœa or by over purgation.

SUMMARY

Experiments are described in which patients' sensations were recorded while the lower sigmoid colon and rectum were distended by inflation of a balloon introduced through a sigmoidoscope.

Distension of the bowel up to 15 cm from the anal orifice (occasionally only 10 cm or as much as 25 cm) caused a sensation of fullness in the rectum giving the patient a desire to pass wind or motion—*rectal type of sensation* Distension above this level produced a purely abdominal sensation, referred to the suprapubic or left iliac region, and simulating a "wind" pain or intestinal colic—*colonic type of sensation*

Interruption of the nerve supply to the rectum and colon by anæsthetic block or operative division showed that the colonic type of sensation is mediated by the sympathetic and the rectal type by the parasympathetic system

Balloon distension causing rectal sensation evoked a contraction of the external sphincter ani which appeared to be partly reflex and partly voluntary This was never produced by colonic distension

A rectal type of sensation never develops in the terminal colon of colostomy cases, but may develop to a small degree in stumps of colon drawn down into the pelvis in cases treated by sphincter saving resections This is probably due to pressure of the distended colon on adjoining pelvic structures and not to a change in the type of sensibility normally inherent in the bowel.

This spurious rectal sensation is unfortunately no adequate substitute for genuine rectal sensation in the maintenance of anal continence Hence, in the performance of sphincter saving excisions, if a good functional result is to be ensured and "sensory incontinence" avoided, it is essential to preserve undamaged not only the sphincter muscles but also at least 6 cm, and preferably 8 cm or more, of anorectal stump with its parasympathetic nerve supply

We are greatly indebted to our colleagues at St. Mark's and St Mary's Hospitals for permission to investigate their cases and to Prof G W Pickering for helpful criticism.

GROUP 10 AREA LABORATORY WHIPPS CROSS HOSPITAL, LEYTONSTONE

Laboratories are now called upon to do so many hæmoglobin estimations that the saving of time without loss of accuracy must be the main consideration in the choice of method Macfarlane et al (1948) showed that, with a neutral grey standard, photometric or colorimetric methods which estimate hæmoglobin as oxyhæmoglobin are as reliable as any routine method and have the additional advantage that hæmoglobin in solution can be converted to oxyhæmoglobin without any special treatment

Using an oxyhæmoglobin method, Bell et al (1945) found that even if 10% of the hæmoglobin is converted into carboxyhæmoglobin or methæmoglobin the alteration in the density reading will be less than 1% They claimed that this is true only if 0 007 *N* ammonia is used as the solvent We have confirmed the magnitude of the error, but with our colorimeter the readings were identical whether 0 007 *N* or 1% ammonia was used King (1946) cites Ammundsen (1939, 1941) as saying that 2–12% of a normal adult's hæmoglobin may be in inactive forms, chiefly carboxyhæmoglobin, methæmoglobin, and sulphæmoglobin But up to 10% of carboxyhæmoglobin will raise the density reading by less than 1% and the same proportion of methæmoglobin will lower it by the same amount, so the errors arising from mixtures of these two substances will tend to cancel each other out Even in a person with severe carbon monoxide poisoning, half of whose hæmoglobin is in the form of carboxyhæmoglobin, when any exertion will precipitate a fainting attack, an uncorrected hæmoglobin estimation would be only 5% too high on the Haldane scale, a correct reading could of course be obtained by passing oxygen through the solution beforehand

E E L TEST TUBE COLORIMETER

With these considerations in view we decided to use the colorimetric oxyhæmoglobin method, and chose the photo electric principle for the sake of accuracy, though errors are more likely to arise in collecting the blood than in estimating the hæmoglobin The simplest instrument seemed to be the 'E E L' test tube colorimeter based on a design of Prof E J King's This is really an absorptiometer, in that it measures the light absorbed by a coloured solution compared with the colourless solvent The light from an incandescent filament passes in turn through a colour filter, a variable aperture, and the test tube containing the solution to be tested, to fall on a light sensitive cell The current produced is measured with a micro ammeter whose scale registers from 0 absorption at full deflection to 100 at no deflection when absorption complete, and the readings on the scale are in direct proportion to the amount of light absorbed In use, the colourless solvent (in this case weak ammonia solution) is put into a standard test tube, and, with the green filter in position, the light is adjusted by varying the aperture until the scale reads 0 The test tube is then replaced by one containing dilute laked blood, and the scale is read again

Reading

There were two ways of obtaining hæmoglobin readings with this instrument (1) One might construct a graph converting the scale readings into hæmoglobin concentrations in this case one would either use dry tubes and measure the appropriate amount of solvent into each with a pipette, necessitating a large stock of tubes, or one would have the tubes marked at an appropriate level when there would be no need for a pipette and undried tubes could be used (2) One might calibrate the tubes in such a way that the result could be found by a simple conversion factor (× 2 for the Haldane scale) The second method is the one of choice, because each tube is calibrated separately, thus eliminating errors due to variations in bore, &c, the tubes need not be dried, and no time is wasted through using pipettes for measuring the solvent

Materials

For this method the following materials are needed

(1) E E L photo-electric test tube colorimeter fitted with an adaptor to take $^7/_{16}$ inch test-tubes
(2) Colorimeter test tubes, $^7/_{16}$ inch (matched)
(3) Green filter (tricolour no 404)
(4) Standard 20 c mm pipettes
(5) Approximately 1% solution of ammonium hydroxide in distilled water

Details of Operation

To 1 ml of the ammonia solution in a calibrated colorimeter tube (see below) add 20 c mm of the blood to be tested and mix Then add ammonia solution to the mark, mix the contents again, and wipe the outside of the tube clean

TABLE I—COMPARISON OF PROPOSED METHOD WITH AN ALKALINE HÆMATIN METHOD ON IDENTICAL DILUTIONS OF THE SAME SAMPLE OF HUMAN BLOOD

Concentration of sample of blood %	Hb reading on Haldane scale	
	By method described	By alkaline hæmatin method
Undiluted	114	114
90	103	102
80	92	92
70	80	80
60	69	68
50	58	56
40	46	46

20	23	23
10	12	11

There is sufficient oxygen dissolved in the solution to oxidise the hæmoglobin present, as may be shown by passing oxygen for 10 minutes through the solution, which will not alter the reading To obtain the zero reading, place a matched tube (kept apart for the purpose), filled with dilute ammonia solution and wiped clean, in the colorimeter, with the green filter in position, switch on the light and open the aperture until the needle registers 0 and remains steady Then replace the matched tube by the tube containing the blood and note the new scale reading (*x*) Repeat the zero reading, and if the needle does not register 0, as may happen if the light sensitive cell has not had time to "settle

down," discard the previous test reading and repeat the process Finally, % Hb (Haldane) = $x \times 2$ This follows from the calibration method described below

Table I shows how hæmoglobin estimations by this method compare with the alkaline hæmatin method (Gibson and Harrison 1945) on identical dilutions of human blood

Correction for bile pigments or other coloured substances may be made by taking a further 20 c mm of blood into physiological salt solution in a calibrated tube, diluting the contents to the mark with salt solution, mixing, and spinning in the centrifuge at 2000 r p m for a minute The reading given by the cell free supernatant fluid is subtracted from the total hæmoglobin reading before the conversion factor is applied or the supernatant fluid may be used as a blank for zero setting the colorimeter

In cases of severe anæmia it is advisable to use 40 c mm of blood diluted in the usual way, when % Hb = x

Calibration of Tubes

(1) 10 ml of venous blood from a healthy person is taken into a tube containing 100 units of heparin and mixed

(2) The hæmoglobin value of this blood is found by the alkaline hæmatin method, the Gibson Harrison standard being used in the photo electric colorimeter This is converted to the Haldane scale

(3) 1 ml of the heparinised blood is added to 90 ml of 1% ammonium hydroxide solution in a volumetric flask, and the volume is made up to 100 ml

TABLE II—VARIATIONS IN READINGS OBTAINED BY SERIOUS INTERFERENCE WITH THE SOURCE OF LIGHT

Concentration of sample of blood (% approx)	Hæmoglobin % on Haldane scale in different lights				Error in coloured lights compared with normal reading in white light (%)		
	White	Yellow	Blue	Red	Yellow	Blue	Red
Undiluted	86	86	86	70	0	0	−19
80	70	70	70	60	0	0	−14
60	52	52	52	46	0	0	−12
40	36	36	36	30	0	0	−17
20	18	18	19	16	0	+5 5	−11
10	9	9	10	9	0	+11	0

(4) 2 ml quantities of this solution (containing 20 c mm of blood) are placed in the colorimeter tubes to be calibrated

(5) The zero reading is obtained as set out above, then each tube in turn is placed in the colorimeter and its contents are diluted until the scale reading is exactly half the known hæmoglobin percentage (Haldane) of the sample of blood With a little practice this can be done very quickly The tubes are then marked at the lower level of the meniscus If hæmoglobin readings in g per 100 ml are required, the tubes may be calibrated so that the scale reading divided by 4 gives the hæmoglobin in g per 100 ml.

DISCUSSION

It will be seen that no standard solution is used for comparison with the unknown, apart from the dilute ammonia solution which gives the zero reading This is because standard conditions are imposed by adjusting the light to give the zero reading, and thereafter identically coloured solutions will always give the same scale reading for each particular instrument Gross variations in light conditions, obtained by tinting the electric light bulb which is the source of light, gave surprisingly low errors (see table II), and such variations would never be attained in normal practice since the energy for the lamp is obtained from the mains via a constant voltage transformer We have used this type of instrument for several years, and an unvarying standard always gives identical readings To test the instrument for accuracy such a standard may be used from time to time, and if the readings always agree one may use the instrument with confidence

The advantages claimed for the method are as follows

Speed—A large number of estimations can be done in a short time The colorimeter tubes need not be dried before use

Accuracy—In table I the results are compared with those of a standard alkaline hæmatin method (which takes much longer) The individual calibration of the tubes excludes the effects of variations in size and shape

Stability—Tubes containing the oxyhæmoglobin solution left standing over night at room temperature gave the same reading next day

Simplicity—The method is reliable in unskilled hands With calibrated tubes there is no need to prepare a graph Even student technicians have obtained consistently accurate results

GUY'S HOSPITAL, LONDON

HELLEBORE, a name anciently given to species of helleborous and veratrums (O E D) has a long established, if somewhat dubious, reputation in the treatment of such diversities as madness, cerebral hæmorrhage, dropsy, and worms *Veratrum album* L and the American hellebore, *V viride* Aiton, contain among others the crystalline alkaloids jervine, protoveratrine, and protoveratridine, and an amorphous alkaloid, veratroidine The extracts, tinctures, or powder, made from the rhizome and roots were hard to prepare in uniform potency, and in 1769 J Cook, writing of *Helleborus fœtidus* in particular, observed "Where it kills not the patient, it would certainly kill the worms, but the worst of it is, it will sometimes kill both" Nevertheless, it has long been known that veratrum viride could lower the blood-pressure, and in consequence it has been administered on occasion to check the convulsions of puerperal eclampsia (Bryant 1935) and the pain of thoracic aneurysm It is of interest that bradycardia was emphasised as an indication of adequate dosage in eclampsia

More recently on account of its digitalis like action, veratrum has been used in congestive heart failure (Löffler et al 1948) The promising results obtained by Freis and Stanton (1948) with veratrum viride in hyperpiesia were followed by studies of its hæmodynamic effects in man (Freis et al 1949) and the preparation by Stutzman et al (1949) of a stable, reproducible, and highly potent extract which was given the proprietary name 'Veriloid'

Veriloid is a mixture of amorphous alkaloids obtained by fractionation, and contains none of the potent alkaloids mentioned above It is biologically standardised according to its vasodepressor effect in dogs Previously veratrum had been assayed in various small animals, a Craw unit being the least amount which would arrest the daphnia heart in systole Since the dog's reactions to veratrum are similar to those in man, it is a more suitable animal for use in standardisation

PHARMACOLOGY

The pharmacological action of the veratrine group of drugs has been studied extensively since purification has made practical their use in hypertension The present position is a little obscure, for the numerous fractions known all have much the same action but with minor and not unimportant differences

in blood-pressure Ultimately the patient was observed as an outpatient

CASE RECORDS

Case 1.—A male bank clerk, aged 39, had complained of frontal headaches in the morning since an attack of amblyopia, lasting two hours, three months previously Although an athlete, he had noticed undue dyspnœa on exertion for six months His mother suffered from hypertension.

On Examination—Optic fundi normal, left ventricle moderately enlarged cardiothoracic ratio 52, blood pressure 240/130 mm Hg, electrocardiogram (E C G) normal Urine contained 0·1 g of albumin per 100 ml., deposit normal Blood urea 35 mg per 100 ml. Intravenous pyelogram showed poor concentration.

Result—During his observation period as an inpatient this man's blood pressure ranged from 200/125 to 180/120 mm. Hg The effect of giving 0·6 mg of veriloid intravenously over a period of 10 min. is shown in fig 1, the systolic and diastolic pressures fell to 70 and 50 mm. Hg at 20 min but were 122 and 88 mm. Hg an hour after the injection Coincident with the fall in blood pressure there was a slowing of the pulse In fig 2 the effects of atropine and ephedrine are shown. Atropine rapidly restored the pulse-rate to normal and at the same time caused a small rise in both systolic and diastolic pressures Ephedrine produced a rapid rise in the blood pressure to above the resting levels

We did not consider that the hypertension and circumstances of this patient warranted treatment with veriloid.

Case 2.—A boy, aged 19, was admitted to hospital in August, 1950, with hypertensive encephalopathy There was no family history of hypertension In 1946 he had acute nephritis, for which he was treated in bed for four months The urine continued to contain albumin and a few red cells, and once there was a frank hæmaturia, so that the boy was in bed for further long periods In February, 1950 he was found semi-conscious, and since then most of his time has been spent in hospital Latterly he has had attacks of headache and vomiting

On Examination.—Poor physique, pallid, with 10·3 g of Hb per 100 ml. No œdema Left ventricle slightly enlarged cardiothoracic ratio 46 Optic fundi papillœdema with exudates and hæmorrhages Urine 0·6 g of albumin per 100 ml red cells and granular casts Blood urea 102 mg per 100 ml standard urea clearance 15% of normal Blood pressure, recorded daily for a month before treatment with veriloid 285–220 mm systolic and 165–130 mm. diastolic, with mean 245/150 mm Hg

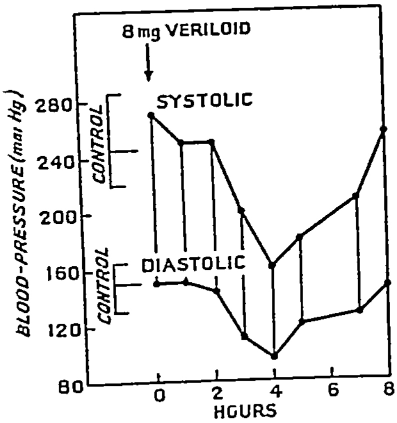

Fig 3—Effect of veriloid 8 mg by mouth on blood pressure (case 2)

The highest lowest, and mean blood pressure readings during the control period are included at the side of this and subsequent graphs.

Result—The patient responded readily to veriloid and fig 3 shows the effect of a single dose of 8 mg by mouth To avoid the possible embarrassment of renal function from sudden lowering of systemic pressure, his blood pressure levels were kept on the high side (fig 4) He has been maintained on veriloid for ten weeks without any significant change in his urinary output or blood urea. There has been much subjective improvement Withdrawal of veriloid was followed by recurrence of the headache and immediate return of the blood pressure to former levels The optic fundi remain unaltered.

Case 3.—A male confectioner, aged 46, who had been known to have hypertension since 1948, was admitted to hospital in 1950 for frontal headaches and shortness of breath. His headaches had begun six months before his admission, and latterly had become so severe as to interfere with his work. He had noted dyspnœa on effort for more than ten years, but in the last five weeks this had become more troublesome and he had taken to his bed In addition, he had angina of effort which came on if he walked 50 yards or so His father died at 46 from hypertensive heart-failure, and his mother at 33 from Bright's disease, one sister had kidney trouble

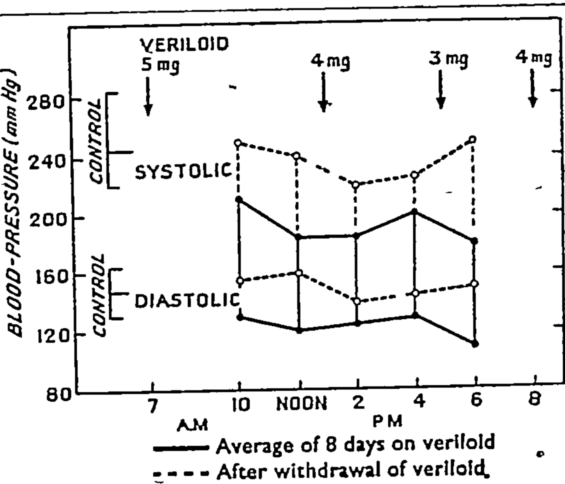

Fig 4—Blood-pressure during eight days on veriloid (continuous lines) and one day without veriloid (interrupted lines) in case 2.

On Examination—Obese and orthopnœic Optic fundi showed grade IV changes (Wagener and Keith 1939) Presystolic triple rhythm present, blood pressure 260/150 mm. Hg Cardiothoracic ratio 54, no hilar congestion. E C G left heart strain Kidneys concentrated to sp gr 1·025 and diluted to sp gr 1·002 Urine 0·1 g albumin per 100 ml, no casts or red cells Blood urea 40 mg per 100 ml During observation period at rest, blood pressure range was 240–210 mm systolic and 130–110 mm. diastolic, with mean of 225/120 mm Hg

Result—This was the first patient on whom we used veriloid, so the initial dose was small and single Less than 10 mg, however, had little effect Fig 5 shows the results of an attempt to adjust the concentration of veriloid so as to keep his blood pressure at a lower level throughout the day When his blood pressure fell to 160/100 mm Hg he felt faint and dizzy With this patient there was considerable variation both in the hypotensive effect obtained and the time taken for the drug to act Fig 6 gives the results with veriloid during five days while he was up and about Coincident with the fall in blood pressure his headaches were considerably relieved and his effort dyspnœa was less marked During ten weeks' observation as an outpatient his progress has been as follows

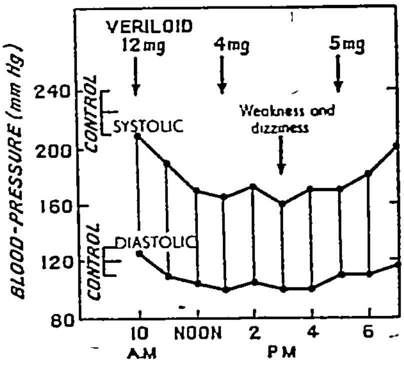

Fig 5—Result of attempt to control blood pressure throughout the day (case 3).

Dose of veriloid (mg) 8 A.M	2 P.M.	8 P.M.	*Blood pressure (mm Hg) at* 5 P.M.	*Toxic effects*
10	4	2	175/105	Morning vomiting faintness
8	6	4	175/105	Nausea after two weeks
6	3	4	215/115	
6	3	4	175/110	

The patient has resumed his work as a confectioner He has a sense of fullness in his head on waking, but his headaches are less severe His angina of effort is now the same as before his admission.

Case 4.—A builder, aged 62, had had severe paroxysmal headaches for two years. His father died from hypertension,

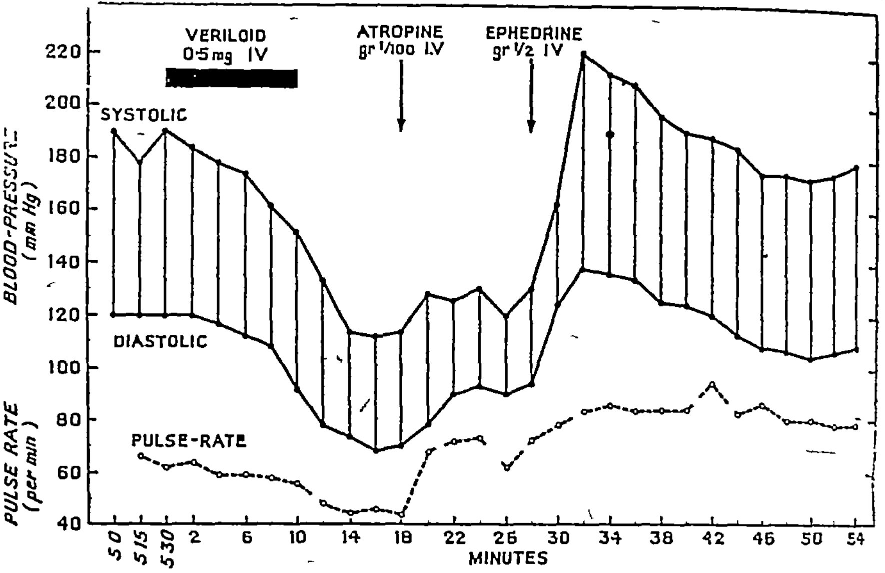

Fig 2—Effects on blood-pressure and pulse-rate of atropine gr 1/100 and ephedrine gr 1/2 i.v in hypotension after veriloid (case 1)

The three major effects of veriloid in man and the dog are hypotension, emesis, and bradycardia

Hypotension—Stutzman et al (1949) suggested that the hypotension is caused by dilatation of the arterioles in skeletal muscle, the splanchnic area, and the skin, together with venous constriction This action is unaltered in dogs by complete atropinisation, bilateral cervical vagotomy, or bilateral denervation of the carotid sinus and body (Stutzman et al 1950), moreover, veriloid produces a further fall of blood pressure in animals already rendered hypotensive by an amount of tetraethylammonium chloride sufficient to block the bradycardia from peripheral vagal stimulation and the pressor response from bilateral carotid occlusion In this respect veriloid seems to differ from the crystalline alkaloids, protoveratrine and veratridine, studied by Meilman and Krayer (1950), who found that their action was largely reflex, involving the peripheral endings of the vagus nerve There is no evidence that veriloid is sympatholytic, the postural and vasomotor reflexes are left intact, and the hypotension is counteracted by ephedrine

Emesis—The emetic action of veriloid, which has been studied in dogs, occurs with either oral or intravenous administration and is unaffected by atropine or ephedrine (Stutzman et al 1950) As would be expected, the drug is less liable to produce vomiting when given after food

Bradycardia—The third effect, bradycardia, has been investigated in dogs and to some extent in man It is probably mediated through the vagus, being abolished by vagectomy in dogs and by atropine in man, and it does not occur in the isolated perfused rabbit heart (Stearns 1950) Increasing dosage in the anæsthetised dog leads to prolongation of the P–R interval, partial heart block, and atrioventricular nodal rhythm, finally 200–500 times the minimal effective dose causes ventricular fibrillation, though this is not seen in the unanæsthetised animal (Stutzman et al 1949) Prolonged administration of veriloid to animals has produced no apparent structural change (Stutzman et al 1950)

METHOD

Our objects have been to observe the effect on the blood-pressure of veriloid given by mouth in gradually increasing dosage thence, by spacing the administration and varying the form in which the drug was given to attempt continuous control of blood pressure at a lower level, to decide in which types of hypertension a response could be expected, to record the toxic effects and finally, when a suitable preparation became available, to study the results of a known concentration from intravenous injection

It was decided to admit the patients to hospital, so as to obtain basal conditions and continuous observation and also for safety's sake, because we were uncertain of the dosage of veriloid required and of the drug's toxicity Ten patients were observed initially in hospital and one as an outpatient only In each case the hypertension was severe, and no patient with a diastolic pressure below 120 mm Hg after five days' rest in bed with mild sedation was included

During the preliminary period in hospital clinical examination, tests of renal function, fluoroscopy of the heart, and electrocardiograms were completed, and the blood pressure was recorded twice daily, as far as possible by the same person, for even a comparative stranger may cause a considerable rise in systemic pressure

When the blood pressure seemed to have reached a stable level, treatment with veriloid was begun At first we tried single doses, but after a considerable amount of experiment we decided on three or four doses in the day When a suitable dosage had been found it was maintained for a few days with the patient ambulant (case 2 was an exception), the drug was then omitted in an attempt to exclude continued stay in hospital as the cause of the fall

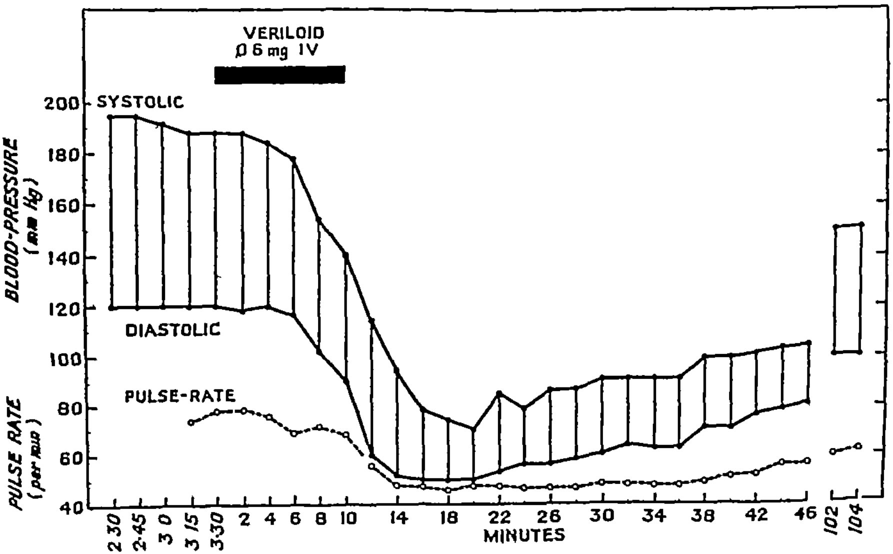

Fig 1—Effect of intravenous veriloid 0·6 mg on blood-pressure (case 1)

n blood pressure Ultimately the patient was observed as an outpatient

METHOD

Our objects have been to observe the effect on the blood pressure of veriloid given by mouth in gradually increasing dosage thence, by spacing the administration and varying the form in which the drug was given to attempt continuous control of blood-pressure at a lower level, to decide in which types of hypertension a response could be expected, to record the toxic effects and finally, when a suitable preparation became available, to study the results of a known concentration from intravenous injection

It was decided to admit the patients to hospital so as to obtain basal conditions and continuous observation, and also for safety's sake, because we were uncertain of the dosage of veriloid required and of the drug's toxicity Ten patients were observed initially in hospital and one as an outpatient only In each case the hypertension was severe, and no patient with a diastolic pressure below 120 mm Hg after five days' rest in bed with mild sedation was included

During the preliminary period in hospital clinical examination, tests of renal function, fluoroscopy of the heart, and electrocardiograms were completed, and the blood pressure was recorded twice daily, as far as possible by the same person, for even a comparative stranger may cause a considerable rise in systemic pressure

When the blood pressure seemed to have reached a stable level, treatment with veriloid was begun At first we tried single doses, but after a considerable amount of experiment we decided on three or four doses in the day When a suitable dosage had been found it was maintained for a few days with the patient ambulant (case 2 was an exception), the drug was then omitted in an attempt to exclude continued stay in hospital as the cause of the fall

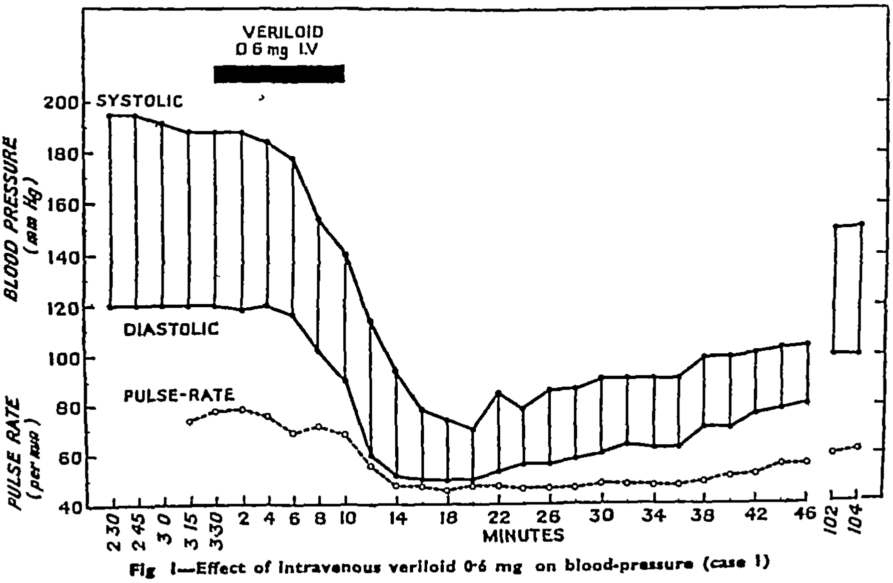

Fig 1—Effect of intravenous veriloid 0·6 mg on blood-pressure (case 1)

discontinue treatment This vagal effect is readily overcome by atropine, it should be borne in mind during the concurrent administration of digitalis Substernal and epigastric discomfort were most troublesome in case 7, they were relieved by hyoscyamine sulphate and were not accompanied by electrocardiographic changes

DOSAGE

Although the blood pressure can be readily lowered by the intravenous administration of veriloid, the oral route offers peculiar difficulties There is individual daily variation in the rate of intestinal absorption, as judged by the degree and duration of the drug's effect on the blood pressure In one patient we thought pylorospasm, perhaps from vagal stimulation, was a factor in delaying absorption The main action of veriloid is exerted three to six hours after ingestion, which necessitates administration three or four times a day and precludes an interval of less than four hours between doses The drug's action is partly cumulative, which calls for frequent observation of the patient in the early stages of treatment with large doses, but the cumulative effect can be used to give a loading dose in the morning The action of veriloid has much in common with that of digitalis

Our procedure is to start with 3, 2, 2, and 3 mg of veriloid given with breakfast (8 A M), lunch (12 30 P M), tea (5 P.M), and late supper (9 P M), or in three doses at breakfast, lunch, and dinner Giving veriloid with food has diminished the tendency to vomit After four days the dosage is adjusted according to the effect produced, but the adjustment must be gradual, for the difference between a profound and a slight hypotensive effect may represent an increase of only 2 mg Nevertheless, an intelligent patient can safely be treated as an outpatient.

Nausea, vomiting, or faintness, if not rapidly relieved by rest is an indication for halving, or if severe omitting, the next dose Nausea may develop in a patient who seems well stabilised, in 2 of our patients a slight reduction in the antecedent dose relieved their nausea without interfering unduly with the hypotensive action of veriloid

DISCUSSION

The precise cause of systemic arterial hypertension remains unknown, but hereditary, psychogenic, endocrine, and renal factors may each determine its production In the benign essential variety the hypertension appears to pass through a labile stage, where psychogenic and endocrine influences are largely operative, to a relatively fixed stage and finally a wholly fixed stage, associated with renal ischæmia and arteriosclerosis There seems to be scant hope of benefiting fixed hypertension, and therapy has been directed to checking the condition in its earlier stages Lumbodorsal sympathectomy seemed a logical approach because it would be expected not only to lower the blood pressure but also to increase renal blood flow But the results on the whole have been disappointing particularly after long term follow up (Evelyn et al 1949), and sympathectomy now has little to commend it, except perhaps in the rare cases of hypertension secondary to chronic pyelonephritis (Platt and Stanbury 1950)

The search for effective hypotensive drugs continues Thiocyanate was first advocated by Treupel and Edinger (1900) and has more recently been reported on by Watkinson and Evans (1947) The use of tetraethyl ammonium salts was described by Stead et al (1948) Paton and Zaimis (1949) noted that hexamethonium and pentamethonium compounds could block ganglionic transmission without exerting any significant atropine-like action Turner (1950), in a clinical study of the methonium compounds, suggested that they had as yet no place in the routine management of patients, though they might prove useful in resistant symptoms related to hypertension Campbell and Robertson (1950) have reported some spectacular results from hexamethonium bromide

If a drug is to be considered satisfactory in the treatment of hypertension it must fulfil the following criteria reduce blood pressure and maintain it at a lower level, act consistently in a high proportion of patients, cause no toxic symptoms, and be easy to administer and control

Possibly because of the more benign course of hypertension in women, it has been suggested that it is not always desirable to lower an unduly high blood pressure, but while we remain ignorant of the first causes of the condition, treatment of the hypertension direct is the sole measure we can apply to relieve the symptoms and avert the failure of heart and kidneys, or rupture of a cerebral artery, which is otherwise the final sequence That by so doing we increase the risk of cerebral thrombosis must be accepted, this risk is similarly present during sleep

The chief source of error in estimating the hypotensive effect of a drug is the considerable variation in blood-pressure throughout the day, apparently independent of external influences, such as excitement or meals, and particularly in hypertensives Evidently veriloid will lower the blood pressure in the great majority of hypertensives, even severe cases Case 6 was an exception for which we can offer no explanation As a result of the vagaries of intestinal absorption it was impossible to control the blood-pressure throughout the day by giving veriloid by mouth, but it was usually possible to convert a severe into a moderate or mild hypertension and at the same time produce well marked symptomatic relief Whether this will affect the development of cardiovascular or renal failure in the younger hypertensive can only be determined after long continued observation At the least it is reasonable to hope that these changes may be retarded

CONCLUSIONS

Veriloid is a potent hypotensive drug which on injection rapidly causes a profound fall in blood pressure For this reason it should prove of value in hypertensive encephalopathy and the convulsions of puerperal eclampsia Given by mouth its absorption is difficult to control and its effect lasts a relatively short time, with the result that uniform lowering of the blood pressure is not readily obtained, but the variations can be kept at a lower level and symptomatic relief is usually attained The margin between therapeutic and toxic levels, where high dosage is necessary, is small and makes the fixed arteriosclerotic type of hypertension unsuitable for treatment Because of vagus action, veriloid is best avoided in the presence of peptic ulceration Its main field of usefulness is in the younger patients with severe benign or malignant hypertension and possibly those with chronic nephritis

We are indebted to the Rexall Drug Co, of Los Angeles, and the Riker Laboratories Inc for supplies of veriloid

On veriloid 26 mg daily, in four doses, his blood pressure ranged from 130 to 180 mm systolic and from 80 to 110 mm Hg diastolic, with a pulse rate about 50, there was considerable symptomatic improvement, but nausea in the forenoon was common The difficulties of continuous control of blood pressure in this patient are illustrated in fig 14

Case 11 —A female checker, aged 39, had had acute nephritis at 24 and again at 34, since when she had remained fairly well until the last three months, when she began to have hypertensive attacks characterised by sweating, palpitation, headache, pallor, and sometimes loss of consciousness

On Examination —Optic fundi grade II arteriosclerosis Heart moderately enlarged, blood pressure 220/110 mm Hg (had been 210/120 mm nine months before) Femoral pulses normal, no cardiac failure E C G left ventricular hypertrophy Urine albumin and granular casts, blood urea 47 mg per 100 ml

Result —This woman's blood pressure with mild sedation was fairly constant at 220/120 mm Hg in the month before outpatient treatment with veriloid was begun The initial dosage of 2 mg b d had no effect, but after a week on 4, 3, and 2 mg daily the blood pressure was 200/105, a week later it was 190/115 and after a further week 135/80 Two, five, and eight weeks later the afternoon readings were 155/90, 145/90, and 150/90 mm Hg respectively During this period there was occasional transitory nausea about midday but no other symptom

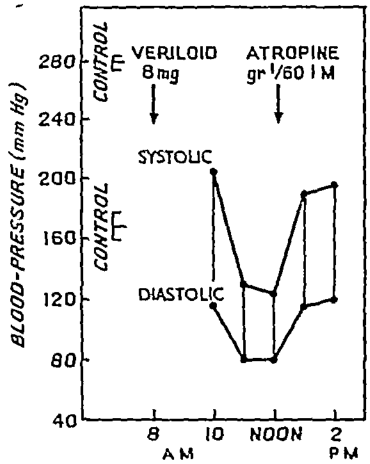

Fig 12—Effect of atropine in presence of hypotensive action of veriloid by mouth (case 9)

RESULTS

Veriloid was given by mouth to 5 men and 5 women with hypertension, and an eleventh patient (case 1) received intravenous veriloid alone The intravenous injection of 0 6 mg of veriloid over a period of ten minutes (fig 1) produced an abrupt and profound fall in the blood pressure, maximal twenty minutes from the start, with a gradual return to previous levels in about two hours There was no postural change in the blood pressure comparable with that after the injection of hexamethonium Together with the fall in blood pressure the patient experienced some flushing of the face and the pulse was slowed, but there was no other symptom Atropine abolished the bradycardia but had only a moderate effect on the blood pressure, whereas ephedrine rapidly restored the pressure to its former levels (fig 2) A single dose of veriloid by mouth may be similar in effect, the hypotensive action occurring two hours or more after ingestion and persisting up to six hours, with a maximal effect between three and five hours after intake (fig 3)

Of the 10 patients treated with veriloid by mouth, 8 showed a definite and at times considerable fall in blood pressure, in case 6 there was no response, and in case 5 the margin between therapeutic and outstanding vagal action was too small to warrant further treatment with the drug No attempt was made to restore normal tension, but it was usually possible to control the diastolic blood pressure at reduced levels and this gave considerable symptomatic relief On withdrawal of veriloid the blood pressure returned to its former levels and the symptoms recurred Case 8, who had malignant hypertension, died of a cerebral hæmorrhage while under treatment

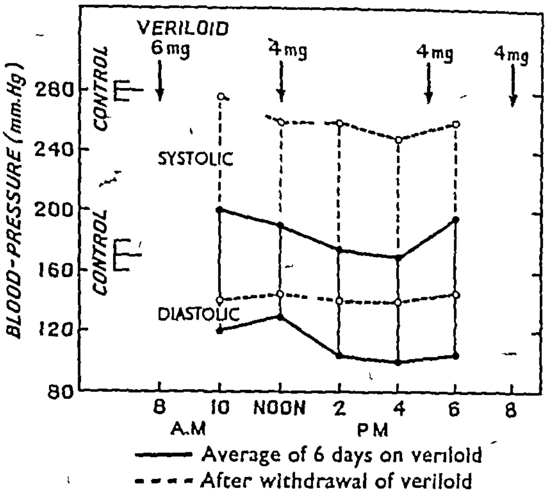

Fig 13—Blood pressures during six days on veriloid (case 9)

Of the 5 patients observed as outpatients for one to three months since their discharge from hospital, in 3 the blood pressure has been kept at a lower level, and these patients *remain considerably improved*, case 11 being an outstanding success Case 7, although symptomatically improved, has been difficult to maintain well *because of nausea, and cannot be considered satisfactory* Case 9, after being considerably improved, developed a cerebral thrombosis and treatment was discontinued

TOXICITY

The toxic effects of veriloid fall into two groups (1) *nausea, vomiting, faintness, and collapse* due to its hypotensive action, and (2) bradycardia and substernal and epigastric discomfort from vagal stimulation Nausea *has been produced at times in all the patients*, and though this is a nuisance it is also a protection against excessive dosage The nausea is not invariably the result of hypotension or of vagal stimulation, for it may still occur where neither of these effects is manifest and may then perhaps be central in origin The 6 patients who developed faintness all did so after a considerable amount of veriloid had produced a well marked hypotensive effect, and ephedrine, by abolishing the hypotension, gave immediate relief

Some slowing of the heart occurred in most patients, but in case 5 the slowing was extreme and caused us to

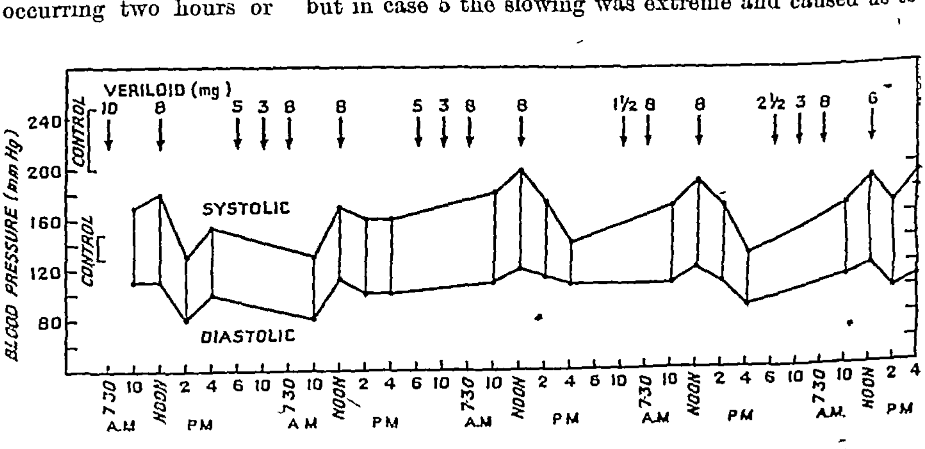

Fig 14—Case 10 shows difficulties of continuous control of blood pressure with veriloid

* *No of abscesses shown in parentheses*

MANTOUX TESTS

Of 7 children under the age of twelve years who were Mantoux tested with 1 in 1000 Old Tuberculin from one to eleven months after an abscess had formed, 2 were positive, one was aged seven, and the other, who was aged sixteen months at the time of the test, had been given penicillin at the age of five months Unfortunately the abscess was not investigated bacteriologically, and this case was possibly tuberculous, though radiography of chest and abdomen revealed no lesions However, it is clear that in 5 of these children the abscesses were not tuberculous.

SENSITIVITY TO PENICILLIN

All the children who were Mantoux tested were also tested for penicillin sensitivity by the intradermal injection of yellow penicillin 500 units in 0 1 ml of distilled water, but the results were negative Of the adult patients 3 had developed urticaria during their penicillin treatment, but 2 of these showed no sensitivity to intradermal penicillin

HISTOLOGY

Six abscesses were excised at stages of development varying from two to twelve months from the time of the penicillin treatment

In general terms the appearances (figs 1 and 2) were those of a foreign body granulomatous inflammation infiltration by lymphocytes, plasma cells, and histiocytes, formation of giant cells, and proliferation of fibroblasts Eosinophils were present in all sections examined and were a prominent feature in some, and there was intense polymorph infiltration of the lining wall of the earlier abscesses

The uniformity of the histological appearances in all the sections suggests that an irritant was the common cause of the abscesses In the older abscesses fibrosis was marked leading eventually in the year old lesion to a fibrous walled cyst with amorphous contents

No tubercle bacilli were seen in any section

SOURCE OF PENICILLIN

No records had been kept of the source and batch number of penicillin given to each patient, but an investigation of the dates of supply of different batches of penicillin to the hospital yielded interesting information

Before October, 1948, all our penicillin was supplied by one manufacturer (source A) Then a further supply was obtained from a second manufacturer (source B) All the penicillin used between the end of October, 1948, and the end of January, 1949, was of this particular batch A second batch was then received from source B, and further supplies were obtained from both source A and source B in March, 1949 The accompanying table shows the monthly incidence of cases in relation to the time at which the penicillin had been given, the number of abscesses caused in these cases, and the source of penicillin It will be seen that there was a striking increase in the incidence associated with one source of penicillin, and in particular with one batch received at the end of October, 1948

There was no more penicillin issued to female than to male wards to explain the preponderance of female cases, nor was the amount of penicillin used in the six winter months sufficiently greater than that used in the six summer months to explain the increased incidence arising from injections given between November and May

DISCUSSION

There are gaps in the account of these chronic abscesses which were unavoidable in the circumstances of the investigation Many of the inquiries were made retrospectively after many months had elapsed

It cannot be claimed, for instance, that a homogeneous series has been presented, or that no single case included in these observations was tuberculous We feel, however, that we have provided enough evidence to conclude that most of the sterile chronic abscesses which develop at the site of penicillin injections are not due to the tubercle bacillus, and that they have distinct clinical and pathological features which suggest a common irritant The evidence also indicates several *predisposing factors* in the development of these abscesses subcutaneous rather than intramuscular injections, a large dose given in a small volume of fluid injected, and, probably most important, the particular batch of penicillin in use

Subcutaneous instead of intramuscular injection is often made in obese patients and in children, and this probably explains the high incidence in women and children

The question of a large dose in a small volume of injected fluid is particularly relevant at present, when the tendency in penicillin therapy is *towards large doses* at relatively long intervals, or, in dealing with penicillin-resistant strains of organisms and with gram negative infections, to massive doses given often For the comfort of the patient the smallest possible volume of injection is usually aimed at, but the implications of this procedure require consideration

Commercial preparations of yellow sodium penicillin vary in potency from 1450 to 1000 units of penicillin per mg of product Since pure penicillin has a potency

CHRONIC NON-TUBERCULOUS ABSCESS AT SITE OF PENICILLIN INJECTIONS

J FIELDING
M R C.P , D P H
ASSISTANT PATHOLOGIST

AUDREY NORRIS
M A , M B Camb
CASUALTY REGISTRAR

PADDINGTON HOSPITAL, LONDON

THE development of tuberculous abscesses at the site of penicillin injections has been reported by Ebrill and Elek (1946), Boquien and Charbonel (1947), Forbes and Strange (1949), Hounslow (1946), Heidenach (1947), Marsh (1949), and Douglas (1950) The last named reported 9 cases

Ebrill and Elek (1946) state that "abscesses sterile on routine examination are not infrequent, but they are not always examined for tubercle bacilli" Inquiries have shown that sterile abscesses at the site of penicillin injections have been seen in many other hospitals

During the first six months of 1949 an unusually large number of abscesses in patients who had received penicillin was seen in the receiving ward of Paddington hospital Altogether 66 abscesses were seen in 28 patients between November, 1949, and February, 1950 Of those 28 patients, 21 had received penicillin as inpatients, and the remaining 7 as outpatients All the abscesses were sterile on routine examination

The following is a report of an investigation into the circumstances in which these abscesses developed

CLINICAL COURSE OF ABSCESS FORMATION

Of 21 adult patients 20 were female and 1 male, 7 were children under the age of twelve years, 4 being two years old or less

The presenting symptom was tenderness on pressure —e g, on sitting There was no spontaneous pain or local hyperæmia

The abscesses were palpable in the subcutaneous fat of the buttocks and thighs, at various depths down to the deep fascia, and varied in diameter from one to three inches No truly intramuscular abscess was seen No accompanying inguinal lymphadenitis was found

From cases of multiple abscesses, and from those in which there were one or more firm small palpable nodules, in addition to a fully formed abscess, it was possible to follow the development of these abscesses At first a non fluctuant nodule is palpable, which may resolve, and probably most of such nodules resolve without further trouble In cases which proceed to abscess formation the nodule slowly enlarges, becomes tender, gradually softens, and involves the skin In half the cases the abscesses discharged spontaneously

60% of the cases observed as fully formed abscesses developed from three to six months after the penicillin injections, but the interval has varied from one to thirteen months The commonest interval was five months

16 patients had more than one abscess, developing at different times, and one patient had as many as seven It is our impression that in patients who have received two courses of injections for different conditions abscesses have formed as a result of both courses, although it is difficult to be sure of this, owing to the multiplicity of injections at each course and the long period of development

Abscesses discharging spontaneously were usually treated with dry dressings only They healed slowly in one to six months, leaving a depressed scar Local heat and other physiotherapy had no apparent effect Incision of the abscess before spontaneous discharge did not alter this course of events, and secondary infection was common In 6 cases, in which the abscesses were aspirated without incision, resolution occurred within three months Up to 2 oz of light brown opaque fluid was removed from each abscess, varying in viscosity, but never as thick as frank pus Repeated aspiration was required in 2 cases

In a further 6 cases the abscess with its fibrous wall was excised, healing occurred by first intention in all but one, in which excision was probably incomplete and which became secondarily infected

DOSAGE AND COURSE OF PENICILLIN

Aqueous yellow sodium penicillin had been given in 63 cases, the number of injections per course varying from four to forty eight In 60 cases the dose per injection had been 200,000–300,000 units in 1 ml of distilled water, 3 patients had received 100,000 units in 1 ml per injection, and 3 had received procaine penicillin 300,000 units per injection No aqueous penicillin had been given in these cases

BACTERIOLOGICAL FINDINGS

Pus, removed after incision, by aspiration, or after excision of the abscess, from 20 abscesses in 15 patients, proved sterile, both aerobically and anaerobically, on routine examination In no case were tubercle bacilli demonstrated either directly or by culture on Löwenstein's medium, or, in 6 cases, by inoculation of guinea pigs A penicillin resistant *Staphylococcus aureus* was grown from fluid derived from a patient with several typical abscesses

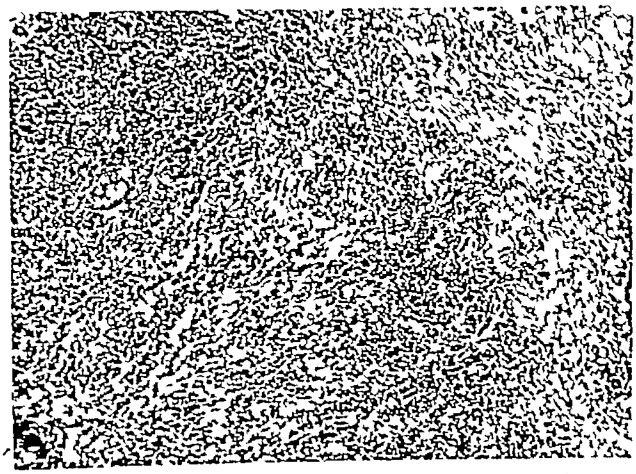

Fig 1—Abscess wall seven months after penicillin (× 70)

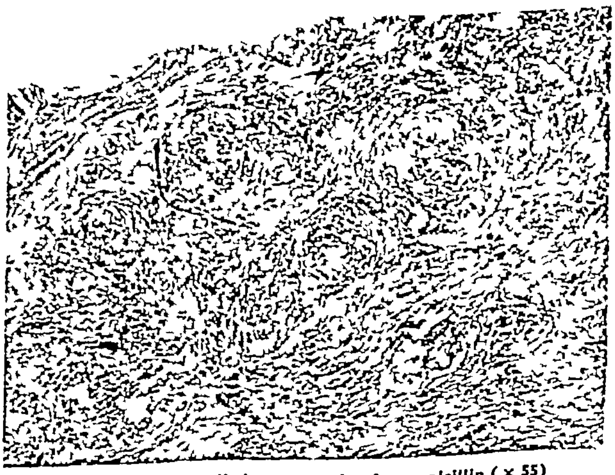

Fig 2—Abscess wall eleven months after penicillin (× 55)

Yaws

Yaws is predominantly a disease of the tropics and is distributed from Central Africa to Burma, Thailand, the East Indies, the Pacific Islands, and the West Indies There is some clinical and pathological evidence that it is distinct from syphilis, but Butler (1936) and Hudson (1946) put forward the view that it is syphilis operating in different circumstances on different soil.

Pinta

Pinta is found in Mexico, Central America, and the northern States of South America, where the number of cases has been estimated at half a million (Varela and Avila 1947) or a million or more (Holcomb 1942) It is caused by *T carateum* which, like *T pertenue* responsible for yaws, is indistinguishable morphologically from *T pallidum* Pinta differs from syphilis even more than yaws does, and perhaps most workers consider it to be a separate disease. Earlier hopes that the in-vitro immobilisation test developed by Nelson and Mayer (1949) may determine specific qualities in the responsible organisms have not yet been confirmed.

Other Examples

While yaws and pinta may have some justification to be considered as separate diseases from syphilis, there are others whose claims are less pressing Such are bejel, the extinct sibbens or button scurvy of Scotland, the radesyge of Norway, the extravenereal syphilis of Turkey (which may still be present in Turkey and possibly in Afghanistan), and the skerljevo of the Balkans, whose remnants may still be observed in Bosnia It is also likely that there are considerable islands of infection in the undeveloped areas of Africa.

In a survey of venereal diseases in Southern Rhodesia, I discovered one such nidus of extravenereal syphilitic infection whose local name is njovera (Willcox 1949) Subsequently I visited Iraq and compared this disease with bejel, which I saw not only in Baghdad but also in the rural Arab tribes of the Ramadi liwa in the Euphrates-Tigris wedge

NJOVERA

The Karanga people of the Fort Victoria and Ndanga districts of the southerly parts of Southern Rhodesia give the name "njovera" to an endemic disease indistinguishable from syphilis and usually contracted in childhood The same word is also used for the venereal syphilis of the towns, but the tribes appreciate that the juvenile disease is contracted in a different manner from the venereal form.

I saw njovera in the Ndanga district and in the satellite clinics east and south east of Fort Victoria in the Chibi and Matibi districts south of Fort Victoria, at Belingwe and Gwanda, both south of Bulawayo, and, under a different name, in the north-west of the country not far from Wankie, which is near to the Zambezi River and the Victoria Falls. Isolated examples of the same condition were observed in Salisbury and other parts, and there is no reason to assume that njovera is confined to the places mentioned but rather that with the development of the African it is tending to die out and assume the customary venereal pattern By hearsay it is also apparently prevalent in adjacent Bechuanaland (Willcox 1950)

Clinical Course

A *primary sore* is not often seen, but a "throwback" is occasionally observed, as in the north-west near Wankie, where a mother while nursing her 18-months-old baby, had a large sore on a nipple and enlarged hard non-tender axillary glands with typical secondary lesions In some clinics cracked nipples and breast abscesses were sometimes diagnosed as njovera by the African orderlies. This seems to indicate that "throwback" infection is sufficiently common for Africans to associate it with the usual form of njovera. Similar stories were told about bejel, which also rarely shows a primary sore, though Akrawi's (1949a) experiments on man indicated that, in experimental bejel at any rate, a definite primary lesion was usual, for it was obtained in 8 of 10 persons inoculated

Njovera is usually first seen in *the secondary stage* and affects the African children of rural areas Lesions are typically present within the mouth or on the lips, where there are mucous patches, and characteristic split papules or small ulcers may appear at the commissures (see figure), and be accompanied by enlargement of the cervical glands and laryngitis The external oral lesions are often confused with angular stomatitis and streptococcal fissures due to a deficiency of vitamins Exactly the same difficulties are encountered in Iraq, where the Arabs diagnosed as bejel an angular stomatitis which was regarded by physicians as due to vitamin deficiency.

Secondary lesions of njovera on lips.

The next most common secondary lesions are those of condylomata lata of the usual form on the vulva, where bilateral plaque-like lesions are not uncommon, and around the anus, groins, and armpits. From these lesions organisms indistinguishable from *T pallidum* may be obtained without difficulty The inguinal glands enlarge to a syphilitic pattern, and sore throat and osteocopic pains are not rare. Secondary lesions of the body are much less often seen, they are usually framboesiform but diffuse and scanty The serum tests for syphilis are positive, and njovera responds to antisyphilitic drugs—e.g., penicillin, neoarsphenamine, and bismuth.

Of 50 persons questioned at Ndanga who admitted to past childhood infection, the lesions present were stated to be on lips and mouth 34, on genitalia and around anus 25, in armpits 13 on face and neck 3, on legs 5 on arms 1, and on the body 3, 1 person remembered having had laryngitis.

At a clinic near the Lundi River, some 70 miles south of Fort Victoria, where the accompanying photograph was taken, a series of children with identical oral and condylomatous lesions was encountered. These ranged from infants a few months old with mothers acknowledged to have had syphilis during pregnancy, through all the age levels to adults whose consorts had recently had syphilis There was no reason why the youngest should not have been suffering from early congenital syphilis, and the eldest from early acquired venereal syphilis, but those patients in the intervening age groups probably contracted the disease by other than sexual activity A boy, aged 7 years, with perianal condylomata, seen elsewhere, admitted to sexual interference, but it is thought that this is an unusual way to acquire njovera, and that usually dirt, flies, overcrowding, communal feeding and implements, and the fact that families sleep huddled together, are responsible for the transmission of the disease

Tertiary lesions may not always be associated with njovera by the patient, although the African may call gummata of the nose and soft palate njovera. Destruction of the nose, with a gangosa-like appearance, may occur of 1650 units per mg, it follows that yellow penicillin contains at present 120–400 mg of impurities per 1,000,000 units An injection of 250,000 units of yellow penicillin is thus accompanied by 30–100 mg of impurities This may be compared with the situation in the early days of penicillin therapy, when the potency of the product was 300–400 units per mg At that time a common dosage was 10,000 units three hourly, and each injection contained about 20 mg of impurities It is probable, too, that the high potency product of today (other than crystalline) contains impurities which have been selectively concentrated during the purification of penicillin

These impurities have not been the subject of many published studies, but they are far from being biologically inert It is well known that individual batches of yellow penicillin vary considerably in the degree of pain caused at the time of injection Ungar (1949) showed that, as measured by the cellular reaction on intraperitoneal injection in guineapigs, yellow penicillin was many times more irritant than crystalline penicillin Yellow penicillin may produce hæmorrhage and tissue necrosis on intramuscular injection in guineapigs and rabbits (Hamre et al 1943) In preliminary experiments one of us has shown that yellow penicillin, potency 1410 units per mg, is about five times more lethal to guineapigs than is the crystalline product 50,000 units intraperitoneally will kill a guineapig weighing 300 g in four to seven days with certain characteristic but inconstant intestinal lesions As little as 5000 units will kill some guineapigs

That there is a relation between tuberculous and non tuberculous abscesses at the site of penicillin injections is a possibility to be considered In the case of tuberculous abscesses the weight of evidence is in favour of exogenous infection introduced with the injected fluid, rather than hæmatogenous spread from a focus elsewhere Whichever of these is correct—possibly both happen at times—the local tissue damage caused by large doses of yellow penicillin may well be a major accessory factor in promoting the growth of a minute inoculum of tubercle bacilli

Schwabacher and Wilson (1937), investigating the minimum infective dose for the most susceptible of laboratory animals, the guineapig, found that an intramuscular inoculum of up to 100 living bacilli produced only very slowly developing disease, often with spontaneous resolution of the primary focus Ten living bacilli could not be relied on to produce disease on intramuscular injection

Kettle (1924) showed that in mice and rabbits given a tuberculous septicæmia the simultaneous subcutaneous injection of silica led to a tuberculous abscess of fixation at the site of injection, whereas some other irritants, although causing local inflammation, were indifferent in this respect

Both these observations, the one from the point of view of exogenous infection, the other from endogenous, suggest that an accessory factor is required for the successful implantation of a minute inoculum of tubercle bacilli We suggest that the irritant variably present in yellow penicillin may be such an accessory factor This would satisfactorily explain the absence of reports of tuberculous abscesses subsequent to other parenteral therapy

SUMMARY

67 chronic abscesses in 28 patients at the site of penicillin injections are reviewed

These abscesses had a characteristic clinical course and were not tuberculous

Their incidence varied with different batches of penicillin

The possible link between tuberculous and non tuberculous abscesses at the site of penicillin injection is discussed

We wish to thank Prof W D Newcomb for most helpful comments, Dr A Beck and Mr G M Gray for their coöperation, and Mr J Hunter for preparing the sections

NJOVERA AN ENDEMIC SYPHILIS OF SOUTHERN RHODESIA

COMPARISON WITH BEJEL

R R WILLCOX
M.D Lond

PHYSICIAN IN CHARGE OF VENEREAL DISEASES DEPARTMENT, KING EDWARD VII HOSPITAL, WINDSOR, CONSULTANT VENEREOLOGIST, ST MARY'S HOSPITAL, LONDON

> "That syphilis and sex are indissolubly linked is only half of the story The other half is that the same disease under other names runs riot through great regions of the earth as a childhood disease without reference to sex"—ELLIS H HUDSON

The problem of syphilitic or parasyphilitic extra venereal diseases caused by organisms morphologically indistinguishable from that of syphilis is world wide The question whether these diseases are syphilis or conditions similar to syphilis has engaged the minds of clinicians and pathologists for as long as the diseases have been recognised

EXTRAVENEREAL DISEASES

Bejel

The disease bejel, affecting the Arabs of the Euphrates and Tigris valleys and adjoining regions of Iraq and Syria, was first described by Hudson (1928) It is caused by an organism indistinguishable from the *Treponema pallidum* of syphilis, has a similar clinical pattern, is associated with parallel serological changes, and responds to antisyphilitic drugs

The clinical course is briefly as follows (Hudson 1946)

> "At some time in early life the Bedhouin child contracts bejel from some other child in the acute stage of the disease The spirochæte is usually passed from host to host by immediate, non sexual contact, and the transfer is favoured by general uncleanliness, total lack of segregation, and the succulence of mucocutaneous lesions Possible auxiliary factors in contagion are the use of the common drinking bowl, the habit of kissing and fondling children and the presence of the domestic fly, the louse, and the flea Lesions often first appear in the mouth but are followed by moist papules in the folds of the skin and by drier lesions on the trunk and extremities Treponemes are easily demonstrable in great numbers in all of these lesions A roseolar eruption has been observed but is rare Late lesions consist of ulceration of the palatal and nasal bones which involve pharynx and often larynx, gummata of the skin, and subcutaneous tissues producing huge ulcers and cicatrices, osteoperiostitis, particularly of the long bones with the *formation of sabre shins,* adenopathy, juxta articular nodules, hyperpigmentation, depigmentation, hyperkeratosis and alopecia An adult who has escaped bejel in childhood is likely to contract it later from a child, often his own The course of the disease in the adult does not differ essentially from that of the child "

The primary stage of the disease is seldom seen

TREATMENT OF PROLAPSED CORD

L WOODROW COX
M B N Z , F R C S , M R C O G
OBSTETRICIAN AND GYNÆCOLOGIST, WALTON HOSPITAL, LIVERPOOL , EXTERN REGISTRAR, LIVERPOOL MATERNITY HOSPITAL

PROLAPSE and presentation of the umbilical cord are rare complications of labour, the incidence being 145 cases in 26,739 labours (0·54%) in twelve years in the Liverpool Maternity Hospital Since it is uncommon, and since some of the cases are seen only after cord pulsations have ceased and the fœtus is dead, obstetricians tend to regard the treatment as theoretical rather than practical

Perusal of many hospital reports shows that the fœtal mortality is commonly about 50% However, on examining the records of this hospital in recent years, I found a smaller mortality than this It seemed that by more active treatment more infants could be saved In the early weeks of my term of office at the hospital three cases were treated actively, by version, but without immediate delivery Two of the infants died It seemed possible that if these had been delivered immediately they would have survived It was therefore suggested that an attempt should be made to obtain a series of 20 or 30 cases without loss of the fœtus To do so meant that the whole team—obstetrician, residents, nurses, and theatre staff, not forgetting the ambulance and the domiciliary services—should be highly efficient

Since some cases of prolapsed cord reach hospital with the fœtus already dead, it is important that any statistical inquiry should pay most attention to those cases where there is an opportunity for treatment As an essential part of the treatment of prolapsed cord is early diagnosis, statistics should be presented with cases divided into the following groups

(1) *Cord not pulsating on admission to hospital*

(2) Cord not pulsating on discovery of prolapse (fœtus alive on admission)

(3) Cord pulsating, discovered at or near full dilatation of the cervix

(4) Cord pulsating, discovered before full dilatation of the cervix

Group 1 is of interest in so far as it is a measure of the awareness of the domiciliary attendants and of the intelligence of the patient

A member of the consultant staff was called on a domiciliary visit to a case of prolapsed cord He arrived at a house to find that the attendant had been sitting for two hours watching a pulsating cord prolapsed outside the vulva and had only called for help when the pulsations ceased *

A multigravida with a bicornute uterus the fœtal presentation being unstable in the latter weeks of pregnancy, had been warned that at the first sign of the onset of labour she must enter hospital She arrived after having had strong uterine contractions for three hours, with the cervix fully dilated, and the cord *prolapsed, not pulsating*

Group 2 is an index of the efficiency of the hospital attendants If heed is paid to the first signs of fœtal distress, and if vaginal examinations are made always on rupture of the membranes, it is unlikely that a case will be missed

A labour ward sister, routinely checking a fœtal heart, noticed a slight irregularity A vaginal examination had been made previously when the membranes had ruptured However, as the presenting part (a vertex) remain unfixed, the sister repeated the vaginal examination and found the cord prolapsed through a cervix dilated to admit only three fingers By the time the house surgeon arrived in the labour ward (a run up one flight of stairs), she was busy setting the operating theatre

Group 3 indicates the operative dexterity of the attendant The discovery of a prolapsed cord at full dilatation may lead him to call for forceps for a hurried delivery But it is no gain if, in extracting the child rapidly to save it, he causes a cerebral trauma and loses it

A multigravida was admitted with a pulsating prolapsed cord The cervix was fully dilated, but the head was not ready for delivery A forceps extraction was quickly performed, but the child was dead Necropsy revealed a tentorial tear *

Group 4—*Around each case in group 4 there can be a* discussion on the method of treatment, and it is to contribute to this discussion that this paper is presented.

After a study of the records of this and other hospitals, the thesis is proposed that delay is dangerous, and that the best plan for saving the fœtus is to deliver the child as soon as the diagnosis has been made From the summary of cases presented below it is seen that only 4 cases were not treated by immediate delivery

(1) A *syphilitic patient with mild toxæmia had labour* induced by rupturing the bag of forewaters The cord was felt beside the head Further examination showed a placenta prævia type I As the patient very badly wanted a living child (having had a macerated fœtus previously), although the chance of a healthy infant was poor, bipolar version was done and a leg was brought down Spontaneous delivery of a living but severely asphyxiated child took place an hour and a half later The child, after a stormy neonatal period, survived

(2) A multigravida, in whom cord prolapse had been detected when the cervix was three fingers dilated, was treated by internal version, and a leg was brought down. The fœtal heart remained regular When the cervix was nearly fully dilated fœtal distress came on and the child was extracted dead

(3) A similar case, where the cervix was four fingers dilated, was treated by internal version and breech extraction The delay in extraction was not much over half an hour from the time of discovery The child was dead.

(4) In a multigravida, having labour induced at term for toxæmia a loop of cord was found beside the head Only a small hole had been made in the bag of forewaters, so as much liquor as possible was drained away, and the cord was pushed up above the parietal eminence inside the membranes Uterine contractions had already started It was decided to await events Normal delivery of a living child took place two hours later

The remaining cases were treated by immediate delivery by whatever method seemed safe In some cases the membranes ruptured and the cord prolapsed at full dilatation of the cervix Delivery was sometimes normal, sometimes with forceps if a cephalic presentation, or by extraction of a breech Sometimes the cervix was incompletely dilated but seemed soft and stretched under anæsthesia , hence, by the time internal version had been done full dilatation was achieved and a breech extraction completed the operation If, however, the cervix was not soft, then without hesitation cæsarean section was performed Every child survived

It is to be expected that this radical treatment may receive adverse criticism because of the increased risk

---

* These cases did not occur in 1948 or 1949

(complete destruction was noted in a girl aged 6 years), as may gummata of the skin or the skull, or their scars, periostitis, plantar lesions, and ganglion formation Two cases of juxta articular nodes were observed in elderly patients

The examples of late bejel demonstrated to me in Iraq included gummata of the soft palate and nasal septum, gangosa like lesions in the adult, and osteo periostitis with sabre tibiæ in the child In both the bejel and njovera cases seen it was impossible to say that these late lesions were not syphilitic

I have purposely omitted any expression of opinion about the possibility of involvement of the cardiovascular and nervous systems Syphilis of both of these systems was encountered in Southern Rhodesia, but in both Rhodesia and Iraq venereal syphilis is rife in the towns, and the matter requires further elucidation, as does the question of transplacental transmission

Incidence

There seemed to be both clinical and pathological evidence in the areas visited that the incidence of childhood njovera was on the decline This is almost certainly due to the treatment facilities offered by the government clinics and reinforced in part by the policy adopted by one physician, which he has pursued for many years, in giving antisyphilitic drugs to all the patients admitted to his clinics

Of 1620 adults 293 (18 1%) had had njovera in childhood and 143 (8 8%) after they had grown up In the latter the disease may have been venereal syphilis, but, even so, it gives a total admitted previous treponematosis rate of 26 9% It was very noticeable, when questioning these patients in 14 rural clinics, that elderly persons nearly always spoke of having had njovera, whereas the young men and women stated far less often that they had had it

Serological surveys are biased by the possibility of yaws, the presence of malaria, and the difficulties attendant on the use of the Kahn test, which was the one generally used under truly “ field ” conditions A previous history of njovera, however, even in the absence of clinical signs, predisposes to a positive serum test for syphilis Thus Kahn tests performed on 156 persons known to have had njovera showed 40 positives (25 6%) and 14 doubtfuls, whereas of 617 persons who gave no history of njovera only 54 (8 7%) were positive and there were 36 doubtfuls

Of serological samplings undertaken during the survey in the njovera area about 13 2% of positives were obtained in 1527 patients tested in nine rural clinics (patients with venereal disease included) If the venereal cases are omitted, the figure was 10 2% These nine clinics were those where mass antisyphilitic treatment had been given through the years In rural areas outside this group 1301 patients, excluding those with venereal disease, were tested in eight clinics and gave 20 3% of positives At two of the institutions in the njovera area there were 40 0% and 49 5% positive tests in 75 and 103 patients respectively

Other figures obtained from a Swedish mission in the njovera area south of Belingwe claimed 75 6% positive of 2140 tested at an outlying clinic in a year, while at the mission hospital in the same year there had been 39 4% positive of 4147 tested The base hospital figure has shown a steady annual decline, having been above that of the outlying clinic in 1929—further evidence of the decreasing incidence

Serological surveys of children in schools adjacent to the clinics where antisyphilitic drugs had been more freely dispensed than is usual gave only 1 9% positive in 360 tested, but 6 3% positive were found in 349 school children serum tested in rural areas outside this region All these schools, however, are situated reasonably near government clinics, and, not only as a result of the facilities offered but also because of increasing civilisation, the chance of children and their parents contracting an extravenereal infection is smaller than in former times

DISCUSSION

Njovera is believed by some to be yaws, indeed it was in search of yaws, which had been reported as being present, that the njovera was encountered I have seen yaws in West Africa and have compared it with syphilis (Willcox 1946) In the secondary lesions (other than condylomata), which are much less frequent in njovera and much less florid than in yaws, in the general absence of primary lesions in njovera, and in the oral manifestations which are so well marked in njovera and are said by some to be slight or even absent in yaws (Chambers 1938, Hermans 1931), the Rhodesian njovera does not closely resemble the West African yaws

On the other hand, yaws has been said to be present not only in Southern Rhodesia but also in neighbouring Portuguese territories Gangosa was encountered in patients from both, and goundou, although not seen by me, was reported as rarely observed Two cases of juxta articular nodes were, however, noted, as was one lesion resembling a primary yaw seen on the chin of an elderly lady at Belingwe

Both diseases may therefore possibly coexist, or if Hudson's (1946) theory of treponematosis is accepted and yaws and syphilis are really the same disease modified by racial, climatic, and sociological conditions, and primitive yaws becomes venereal syphilis as the only hope of survival for the treponeme, with intermediate forms still present as bejel, then we may have here examples of the transition in progress

Hudson (1946) considers bejel as a manifestation of treponematosis caused by *T pallidum*, and Akrawi (1949 a) believes it to be syphilis, but these viewpoints are not necessarily contradictory I think that njovera is syphilis and probably identical with bejel Both njovera and bejel are primarily diseases of children, and in both of them the primary stage is usually absent and “ throw backs ” occasionally present, and in both of them the secondary stage is identical, with genital and anogenital condylomata, mucous patches in the mouth and on the lips, and split papules or ulceration at the commissures of the lips In both diseases other secondary lesions on the body are less frequent The later manifestations of bejel seen included gummata of bone and soft tissue, osteoperiostitis, gummata of the soft palate and nasal septum, and gangosa like lesions These, if much more numerous in the bejel area, are of the same general pattern as encountered with njovera Juxta articular nodes in bejel have been reported by Hudson but have not been seen by Akrawi (1949b) They were but rarely seen in Southern Rhodesia by me

SUMMARY

Njovera, an extravenereal syphilis encountered in certain parts of Southern Rhodesia, is described As a result of government treatment facilities and improving social conditions, its incidence is believed to be declining

A comparison of njovera with bejel in Iraq shows that they are similar if not identical It is believed that both conditions are in fact syphilis

The investigation in Southern Rhodesia was part of a larger survey undertaken for the Government of that country I am indebted to Dr R M Morris, the Secretary for Health, and to many doctors there especially Dr J H Kennedy, of Ndanga for their many kindnesses and help The serological tests were done by Mr E A Boulter The work in Iraq was part of a mission performed for the World Health Organisation, and special thanks are given to the Ministry of Social Affairs of Iraq and to Prof F Akrawi, of Baghdad

A CASE OF TRUE HERMAPHRODITISM

A W Capon
M.A., M.B Camb, M R C.P
LATE MEDICAL REGISTRAR, MILE END HOSPITAL, LONDON

True hermaphroditism is rare, only 40 authenticated cases having been published According to Hinman (1935) it may be of three types

- A. Bilateral, with ovary and testis on both sides, either separate or united (ovotestis)
- B Unilateral, with testis and ovary, separate or united, on one side, and an ovary or testis on the other
- C Lateral or alternating, with a testis on one side and an ovary on the other

Of the 40 published cases 11 were bilateral, 14 unilateral (7 with an ovary, and 7 with a testis, on the opposite side from an ovotestis), 11 were lateral, and 4 had an ovotestis on one side, the other gonad remaining unidentified (Weed et al 1947) In the case reported here the right gonad was an ovotestis and the left an ovary

CASE RECORD

The patient, aged 29, reported to the outpatient department complaining of lassitude and palpitation, symptoms which proved to be due to a mild anxiety state Preliminary examination showed female bodily configuration and maldeveloped genitalia

History —He was brought up as a boy At the age of 8 he became aware of the defective development of his external genitalia, and from that age onwards he strove to prevent the defect from becoming known He does not remember the matter being discussed at home at any time At school he was keen on games, and was captain of the school football team, but he gave up football and swimming at the age of 15 owing to the development of his breasts His voice altered somewhat at this age, becoming deeper, but it did not develop a normal masculine pitch. At 11 he won a scholarship to a secondary school, and he was preparing for a career as an architect, but he had to leave school at 15 owing to financial difficulties He then started work as a plasterer, and he has continued with this occupation, though he has changed his job on many occasions because he becomes unsettled if he stays in one place for long

His interests have always been heterosexual, and he married at the age of 26 His marriage is regarded by him as satisfactory, and intercourse is practised two or three times a month.

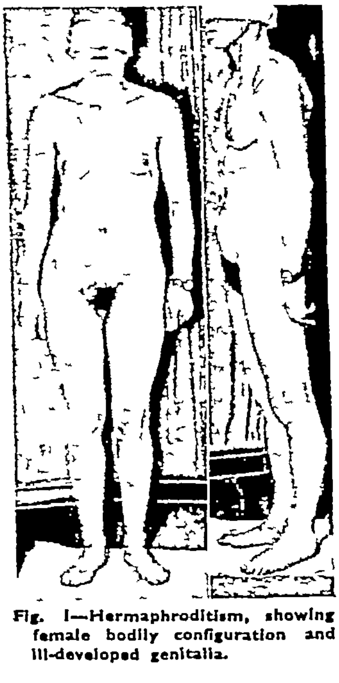

Fig. 1—Hermaphroditism, showing female bodily configuration and ill-developed genitalia.

Owing to the position of his urethra, he has always voided his urine standing up About three years ago he noticed a slight bloodstained discharge from the urethral orifice, and this was repeated at irregular intervals The bleeding later became more regular, with a cycle of about 28 days, and lasting 3 or 4 days Rarely was the bleeding sufficient to appear externally, most of the discharge being passed at the time of micturition. No associated symptoms occurred at these times

Genital and axillary hair started to grow at the age of 16, but he has rarely had to shave the soft hair which appeared somewhat later on his face There is no history of genital defects in other members of his family

On examination the patient was found to have a female type of body, with well-developed breasts (fig 1) containing palpable glandular tissue His skin was smooth, and he looked younger than his age There was a little soft hair in the beard area The axillary hair was scanty, and the pubic hair was of female distribution His height was 5 ft 4½ in, weight 135 lb, span 5 ft 6 in, length of upper limb 24 in., length of lower limb 37 in., and he measured 34½ in round the chest, 27½ in. round the waist, and 37 in round the hips Muscular development was within normal limits for a man A right incomplete indirect inguinal hernia was present Physical examination revealed no other defects apart from those mentioned above, and those of the genitalia

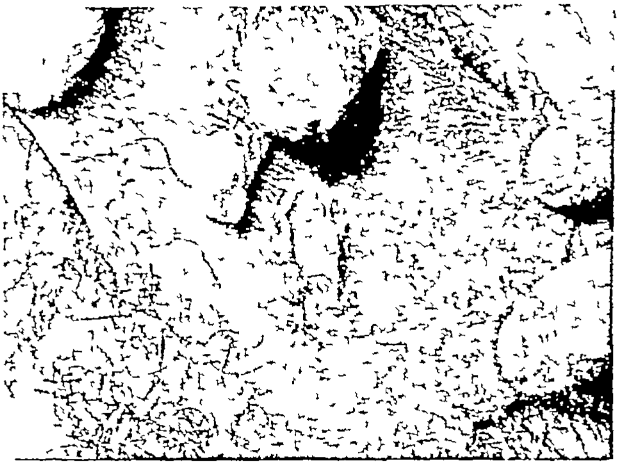

Fig 2—Hermaphroditism showing short penis and urogenital sinus leading to female genitalia.

Under general anæsthesia it was found that the labioscrotal folds met anteriorly over the root of the " penis," which was about 2 in long No gonads were palpable in the labioscrotal folds The glans projected beyond the folds and exhibited a small depression in the normal site of the opening of the male urethra The glans was uncovered, the prepuce being represented by a loose fringe of skin attached all round behind a well marked corona A tag of skin hung down from the prepuce on the right side Rudimentary

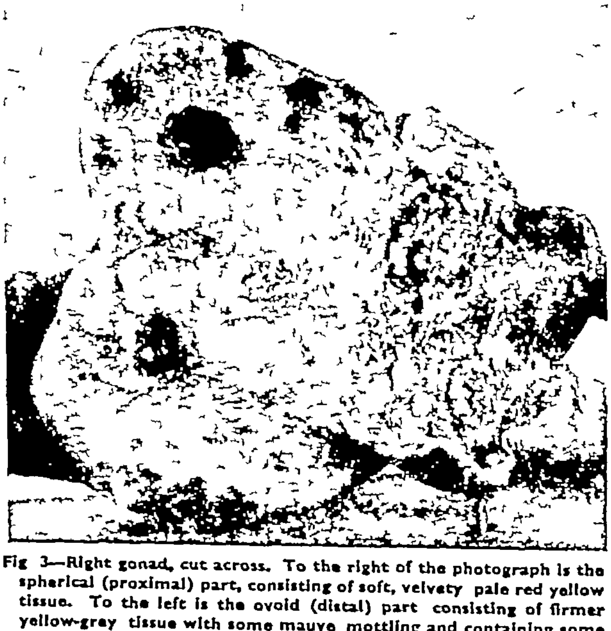

Fig 3—Right gonad, cut across. To the right of the photograph is the spherical (proximal) part, consisting of soft, velvety pale red yellow tissue. To the left is the ovoid (distal) part consisting of firmer yellow-grey tissue with some mauve mottling and containing some small cysts filled with blood clot. The two parts are separated by a narrow indefinite white zone.

of operating on a hurriedly prepared patient With modern facilities this risk should not be great Surgical instruments in most hospitals are kept sterilised ready for use Anæsthesia, when intravenous agents are used, atropine, curare, and 'Kemithal' (thialbarbitone), with intratracheal tubes and aspirators in readiness, is not the hazard of yesteryear

RESULTS

The following is a summary of the results in the period from Jan 1, 1948, to Dec 31, 1949

Number of cases	35
Infants born	39

In 4 sets of twins one infant of each set had a prolapsed cord the presentation of the remaining infant was normal and no mishap occurred in the delivery of this infant

Infants stillborn (cord pulsating on admission)	2 (5 7%)
Infants stillborn (cord not pulsating on admission)	2 (5 7%)
Neonatal deaths	0
Gross fœtal mortality	4 (11 4%)
Group 1 (cord not pulsating on admission to hospital) 2 cases	
Stillbirths	2
Group 2 (cord not pulsating on diagnosis) 0 cases	
Group 3 (cord pulsating discovered at or near full dilatation of cervix) 12 cases	
Normal delivery	3
Forceps delivery	2
Breech extraction	7
Stillbirths	0
Group 4 (cord pulsating discovered before full dilatation of the cervix) 21 cases	
Immediate delivery	
Cæsarean section	13
Internal version and breech extraction	4
Stillbirths	0
Delayed delivery	
Internal version and breech extraction	3
Normal delivery	1
Stillbirths	2

ILLUSTRATIVE CASES

Typical cases are the following

Case 1—A breathless urchin arrived at the hospital with a note from the district midwife that a cord had just prolapsed The house was barely a stone's throw distant While the telephonist was calling the ambulance, two house surgeons ran to the house, prepared to effect delivery immediately if conditions were suitable At the same time the operating theatre was prepared both for cæsarean section and for vaginal delivery

The patient, a multigravida, was in labour The cord was found to be pulsating strongly, but the cervix was only about four fingers dilated In a minute or two the ambulance arrived, and the patient was moved to hospital There, atropine was given intravenously, and after the usual preparations an anæsthetic was administered During internal version the cervix was dilated completely, and a living child was extracted as a breech

Case 2—A doctor telephoned to say that he had a patient in a nursing home whose waters had just broken, and the cord was prolapsed The ambulance was immediately dispatched, and preparations were made for vaginal delivery or for cæsarean section On arrival, the patient was taken directly into the operating theatre, where the pulsating cord was found to be prolapsed through a cervix dilated to admit two fingers Anæsthesia was induced with curare and thialbarbitone, and cæsarean section was done A living child was delivered

Case 3—A patient in the antenatal ward awaiting a repeat cæsarean section complained of backache It was thought that labour might be starting and a vaginal examination was made The cervix had begun to dilate, and in the intact bag of forewaters the cord was presenting Within an hour cæsarean section had been completed and a living child delivered

To save so many of these children the conditions of work must be satisfactory As nearly as possible all unnecessary risk is eliminated in this hospital The facilities for immediate vaginal or abdominal operations are always ready An expert anæsthetist is available at a moment's notice There is always in the building an obstetrician capable of taking the responsibility for, and trained to do, any operation No mishap has occurred with any mother in this series, and the puerperia have been normal

ÆTIOLOGY

Twins—Prolapse of the cord of the first twin occurred thrice, and of the second twin once

Breech Presentation—Prolapse of the cord occurred six times in cases of breech presentation In five of these the cervix was fully or almost fully dilated, and a breech extraction was done

Transverse Lie and Compound Presentations—In these cases prolapsed cord occurred four times, three times the cervix permitted vaginal delivery In addition there was one case with a bicornuate uterus where the lie was longitudinal on admission

Disproportion was associated with three cases, and cæsarean section was performed

Surgical induction of labour was followed by prolapse of the cord in six cases two were for toxæmia, two for expected erythroblastosis, and two for breech presentation (already mentioned) to avoid postmaturity Two cases were treated by cæsarean section

Cases Otherwise Regarded as Normal—Four occurred when the cervix was fully dilated, and nine when the cervix was incompletely dilated

DISCUSSION

The argument here proposed, that the child can be saved in almost every case, is applicable only to urban communities with a highly efficient hospital service Other methods, with different results, must perforce prevail in less densely populated countries In those circumstances any measure that yields a fœtal mortality of less than 100% can be said to have its place

The greater share of praise for the success gained in this series is due to the nurses and to the ambulance service for their speed in performing their tasks Only a modicum need be offered to the operators concerned in the deliveries, and that not for speed, but for forbearance from haste, so that the infants were extracted with all due care, still living It is fitting to record that, once "immediate delivery" became the practice, no infant was lost in an unbroken series of nearly 30 cases

SUMMARY

35 cases of prolapse or presentation of the cord are reviewed

The fœtus was lifeless on admission in 2 cases 5 7%

No infant was lost when delivery was performed immediately

The gross fœtal mortality was 11 4%

My thanks are due to the visiting medical staff of the Liverpool Maternity Hospital for permission to treat many of these cases and to record the results Four cases were in private patients, and were treated by the four consultants concerned

---

" During my student days I had the good fortune to be taught by a physician who had a clear appreciation of the 'functional aspects of disease' A patient, say John Smith, had been allotted to me as a clinical clerk Both the history and physical examination indicated that he had lobar pneumonia, and therefore when asked by the clinician what the patient was suffering from, I confidently replied that he had pneumonia To my surprise the answer was 'No, John Smith has not got pneumonia, but pneumonia has John Smith The physician then proceeded to explain that, although John Smith did in fact have pneumonia, there were many other factors concerning him which might be of equal or even greater importance "—Dr LESLIE HURLEY, *Med J Aust* Feb 17 1951, p 254

A CASE OF TRUE HERMAPHRODITISM

A W CAPON
M.A., M.B Camb, M.R C.P
LATE MEDICAL REGISTRAR, MILE END HOSPITAL, LONDON

TRUE hermaphroditism is rare, only 40 authenticated cases having been published. According to Hinman (1935) it may be of three types

A. Bilateral, with ovary and testis on both sides, either separate or united (ovotestis)

B Unilateral, with testis and ovary, separate or united, on one side, and an ovary or testis on the other

C Lateral or alternating, with a testis on one side and an ovary on the other

Of the 40 published cases 11 were bilateral, 14 unilateral (7 with an ovary, and 7 with a testis, on the opposite side from an ovotestis), 11 were lateral and 4 had an ovotestis on one side, the other gonad remaining unidentified (Weed et al 1947) In the case reported here the right gonad was an ovotestis and the left an ovary

CASE RECORD

The patient, aged 29, reported to the outpatient department complaining of lassitude and palpitation, symptoms which proved to be due to a mild anxiety state Preliminary examination showed female bodily configuration and maldeveloped genitalia

History—He was brought up as a boy At the age of 8 he became aware of the defective development of his external genitalia and from that age onwards he strove to prevent the defect from becoming known. He does not remember the matter being discussed at home at any time At school he was keen on games, and was captain of the school football team, but he gave up football and swimming at the age of 15 owing to the development of his breasts His voice altered somewhat at this age, becoming deeper, but it did not develop a normal masculine pitch. At 11 he won a scholarship to a secondary school, and he was preparing for a career as an architect, but he had to leave school at 15 owing to financial difficulties. He then started work as a plasterer and he has continued with this occupation, though he has changed his job on many occasions because he becomes unsettled if he stays in one place for long

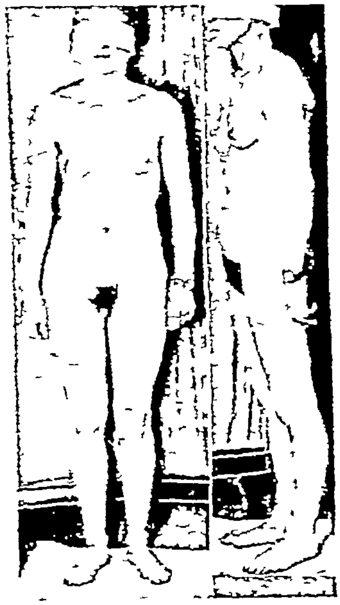

Fig. 1—Hermaphroditism showing female bodily configuration and ill-developed genitalia.

His interests have always been heterosexual, and he married at the age of 26 His marriage is regarded by him as satisfactory, and intercourse is practised two or three times a month.

Owing to the position of his urethra, he has always voided his urine standing up About three years ago he noticed a slight bloodstained discharge from the urethral orifice, and this was repeated at irregular intervals The bleeding later became more regular with a cycle of about 28 days, and lasting 3 or 4 days Rarely was the bleeding sufficient to appear externally, most of the discharge being passed at the time of micturition. No associated symptoms occurred at these times.

Genital and axillary hair started to grow at the age of 16, but he has rarely had to shave the soft hair which appeared somewhat later on his face There is no history of genital defects in other members of his family

On examination the patient was found to have a female type of body, with well-developed breasts (fig 1) containing palpable glandular tissue His skin was smooth, and he looked younger than his age There was a little soft hair in the beard area The axillary hair was scanty, and the pubic hair was of female distribution His height was 5 ft $4^{1}/_{2}$ in., weight 135 lb, span 5 ft 6 in., length of upper limb 24 in., length of lower limb 37 in., and he measured $34^{1}/_{2}$ in round the chest, $27^{1}/_{2}$ in. round the waist, and 37 in. round the hips. Muscular development was within normal limits for a man A right incomplete indirect inguinal hernia was present Physical examination revealed no other defects apart from those mentioned above, and those of the genitalia

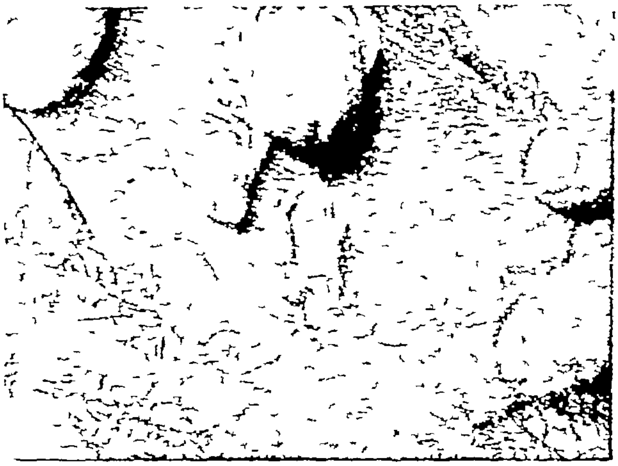

Fig 2—Hermaphroditism showing short " penis " and urogenital sinus leading to female genitalia.

Under general anæsthesia it was found that the labioscrotal folds met anteriorly over the root of the " penis " which was about 2 in. long No gonads were palpable in the labioscrotal folds The glans projected beyond the folds and exhibited a small depression in the normal site of the opening of the male urethra The glans was uncovered, the prepuce being represented by a loose fringe of skin attached all round behind a well marked corona A tag of skin hung down from the prepuce on the right side Rudimentary

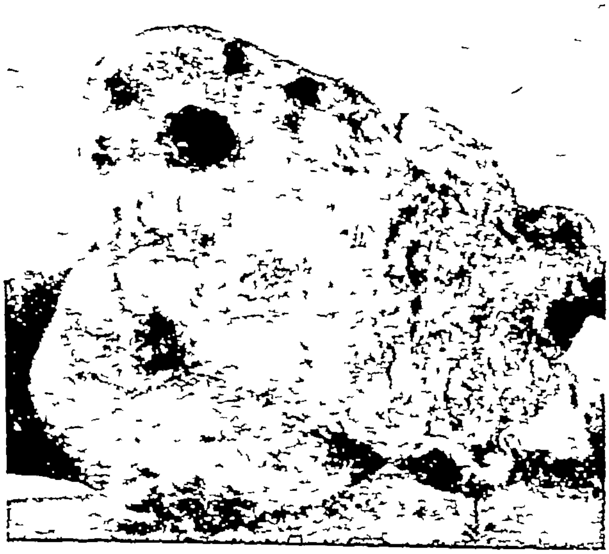

Fig 3—Right gonad, cut across. To the right of the photograph is the spherical (proximal) part, consisting of soft, velvety pale red-yellow tissue. To the left is the ovoid (distal) part, consisting of firmer yellow-grey tissue with some mauve mottling and containing some small cysts filled with blood clot. The two parts are separated by a narrow indefinite white zone.

labia minora were present, and between them posteriorly was a circular orifice $^1/_4$ in in diameter (fig 2) which opened into a cavity which was regarded as a persistent urogenital sinus A urethral orifice was observed at a depth of $^1/_2$ in from the surface Posterior to this was the vaginal opening, this being slightly constricted by a muscular ring which gripped the little finger The vaginal cavity was 4 in long and extended upwards and backwards In the vaginal vault was a small cervix with a patulous os and larger posterior, and smaller anterior, lips

Cytoscopy revealed no abnormality Iodised oil run into the vagina passed into the uterus and fallopian tubes, and radiography gave the impression of a bifid uterus , but this study was inconclusive During cytoscopy the " penis " became erect, and it was seen that erection was limited by a tight frenum Rectal examination had previously demonstrated the presence of a small uterus and cervix

Operation (Mr S Willson Holmes, F R C S) —As the patient was reluctant to submit to any major operation, he was advised to have a plastic operation on the " penis " and a repair of the right inguinal hernia At this time the diagnosis was one of ovarian pseudo male hermaphroditism Through a right inguinal incision the sac of the hernia was exposed and opened after division of the deep epigastric vessels It was not considered justifiable to damage the conjoined tendon, and examination of the pelvic contents was incomplete It was impossible to ascertain the nature of the gonad on the left side A small uterus with supravaginal cervix was palpable, the whole structure being 2 in long and 1 in broad The uterus was median and single, and the arrangement of the pelvic peritoneum was like that found in a normal female The right fallopian tube was 6 cm long and normally fimbriated, and showed the normal relationship to a gonad The right gonad, $^1/_2$ in of broad ligament with the fallopian tube and the hernial sac were removed, and the hernia was repaired The right gonad (fig 3) consisted of a spherical part 1 2 cm in diameter united to an ovoid part (2 4 × 1 7 cm) At operation there was no evidence of any intrapelvic elements of the male genital tract

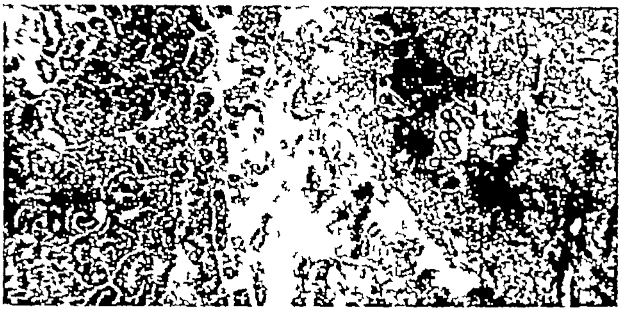

Fig 4—Ovotestis, showing both ovarian and testicular tissue (× 20)

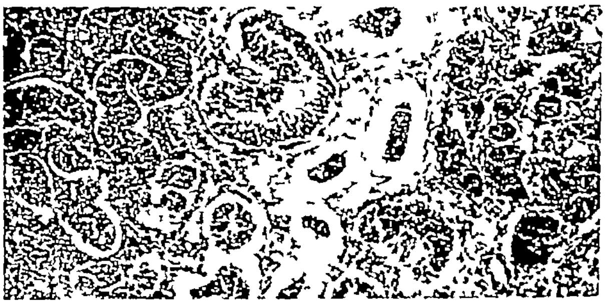

Fig 5—Ovotestis showing testicular tissue (× 100)

Histology (figs 4–7) —The spherical part of the right gonad consisted of seminiferous tubules, some well formed but mostly showing various degrees of atrophy, with replacement by hyaline tissue Islets of well defined testicular interstitial cells were present The ovoid part of the gonad was typically ovarian and showed a well formed graafian follicle with ovum, corpora albicantia, a corpus luteum undergoing change to a corpus albicans, small cystic follicles, and numerous primordial ova The specimen was therefore an ovotestis

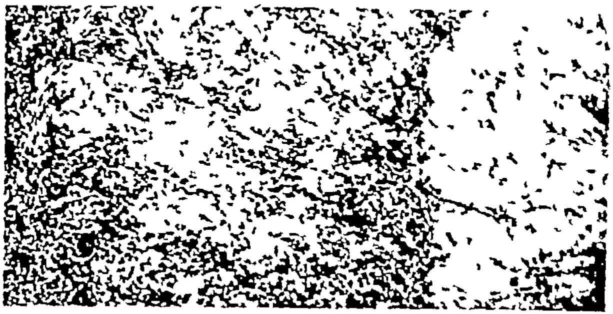

Fig 6—Ovotestis, showing ovarian tissue with a corpus luteum undergoing change to a corpus albicans (× 100)

Investigations —Radiography of the chest showed no abnormality, but radiography of the pelvis showed a partial spina bifida of the first sacral vertebra, a small sacrum, and a wide pelvis of gynæcoid type The urine contained no abnormal constituents , sp gr 1 024 A blood count showed red cells 4,440,000 per c mm , Hb 74%, colour index 0·84, and white cells 9800 per c mm (neutrophils 62%, eosinophils 3%, basophils 1%, lymphocytes 28%, monocytes 6%)

Progress —Menstrual bleeding occurred after operation and lasted six days In view of this, and the removal of testicular tissue at operation, it was decided to institute androgen therapy The patient was given injections thrice weekly of testosterone propionate 25 mg , and this treatment was continued for three months, after which an implant of 1 g was made Six months later the patient had gained 8 lb in weight, and he needed to shave once a week instead of very occasionally Menstruation was much reduced but not completely inhibited, and a year after the initial investigation more radical surgical treatment was advised and accepted

Second Operation —Mr S Willson Holmes did a total hysterectomy and left salpingoöphorectomy The uterus was slightly smaller than in the normal adult female, and the fallopian tube and ovary were grossly normal, section of the ovary showing several small cysts Microscopical examination of the uterus showed normal endometrium in the proliferative non secretory phase, and the ovarian tissue was also normal there being no evidence of testicular tissue

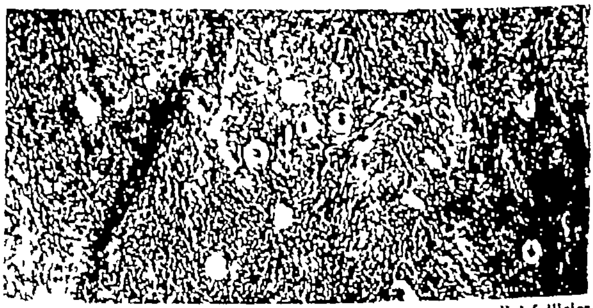

Fig 7—Ovotestis, showing ovarian tissue with primordial follicles (× 100)

COMMENTS

The general appearance and genital development in this patient are predominantly female, but the psychological outlook is male This is in accordance with the observation made by McKenna and Kiefer (1944) that in most cases of true hermaphroditism the libido and emotions depend on the person's upbringing Investigation at any early age would have disclosed the predominantly feminine sexual characteristics, and surgery could have removed the " penis " and constructed a normal opening of the vagina

In all cases the sociological background must be considered before undertaking treatment In this case the patient, aged 29, was the male partner of a marriage, and was predominantly masculine in outlook It was therefore important that he should continue to regard himself as essentially male, or impotence would almost certainly have resulted

It would have been more satisfactory to remove the terus, fallopian tubes, and ovarian tissue at the first peration, but the patient refused this, and technically t would have been impossible to ensure an adequate lood supply to the testicular portion of the ovotestis n the right side

Replacement therapy with testosterone propionate will be necessary for the rest of the patient's life

The association of inguinal hernia with hermaphroditism has been previously reported (Weed et al 1947) It is interesting to note the association with spina bifida occulta

SUMMARY

A case of true hermaphroditism is described, including the sociological and psychological background

The main points were the presence of a true ovotestis on the right side, with an ovary on the left, associated with predominantly female physical characteristics combined with a male psychological outlook

I wish to thank Dr Raymond Greene for his guidance, Mr S Willson Holmes for the surgical investigation and treatment, Dr V Pugh for help in the preparation of the specimens, Dr Louis Steingold for the reports on the ovotestis and photomicrographs, and Dr W Gordon Sears, senior physician and medical superintendent, Mile End Hospital, for his help and encouragement The clinical photographs were taken by Nucleus Photographic Specialists Ltd, London, E C 1

Reviews of Books

Diseases of the Heart and Circulation

PAUL WOOD, O B.E, M.D, F.R C P director, Institute of Cardiology, London. London Eyre & Spottiswoode 1950 Pp 589 70s

IT would be difficult to get so comprehensive an account of this subject into fewer words On many aspects of cardiology Dr Wood is able to strengthen his account from his own original work, but everywhere he quotes the views of others Indeed, perhaps fewer references and a more dogmatic statement would be better suited to the student, though it is doubtless hard to know where to draw the line when the requirements of examiners and personal modesty have to be considered Dr Wood opens with chapters on clinical examination, X-ray appearances, and electrocardiography, in which the theory of the normal curve and the principles underlying abnormalities are briefly considered, cardiograms are more fully described in the chapter on disorders of rhythm as well as throughout the book The chapter on heart-failure is excellent, but in dealing with triple heart sounds (or gallop rhythm) remarks about syllables per poetical foot only serve to mystify In the remaining sections the account is mainly on accepted lines The book is profusely and beautifully illustrated, and in every sense a fine production

Neoplasms of Bone

BRADLEY L COLEY, M D, attending surgeon, bone tumour department, Memorial Hospital for Cancer and Allied Diseases, assistant professor of clinical surgery, Cornell New York Paul B Hoeber London Cassell 1949 Pp 765 £6 10s

THE bone sarcoma registry, while advancing and greatly increasing our knowledge of bone pathology, has led rather to greater complexity than clarity, and what was a few years ago a very simple field in pathology has become difficult to experts and almost incomprehensible to the pathology of the practising surgeon Thus a great want has been supplied in this capable book, in which Professor Coley describes and associates the clinical and pathological features of neoplastic bone disease He is fitted by birth, interest, and exceptional experience to write such a book, and in him we have the experienced pathologist and surgeon combined In this comprehensive work he begins with the latest classification, and the biochemistry of bone neoplasms, and then deals with the various innocent, malignant, and "tumour-like" swellings (and the chapter on fibrous dysplasia is masterly) The later chapters discuss the various tumours in special situations, the various modes of treatment, and the results achieved in large series of cases Too many books on bone pathology confuse rather than clarify, but here description is uniformly full and clear, so that every type of tumour, however rare, stands out as an entity Not only orthopædic, but general surgeons—to whom bone tumours, common or exceptional, are relatively rare—will gain greatly from possession of this work

Results of Radium and X-Ray Therapy in Malignant Disease

Third Statistical Report from the Radium Institute, Manchester Compiled by RALSTON PATERSON, C.B.E, F R C S E, MARGARET TOD, F R C S E, MARION RUSSELL Edinburgh E & S Livingstone 1950 Pp 167 10s 6d

THIS is primarily a statistical report on radiotherapy at the Christie Hospital and Holt Radium Institute, Manchester, with a plea for a different way of presenting results The generally accepted method, which allows personal opinion and failure of follow-up to influence survival-rates, has been discarded, and in its place the use of crude rates, corrected by age, has been adopted. To obtain the age factor for the correction of the five-year survival rates for deaths due to intercurrent disease, age tables have been rearranged on the pattern used in the General Register Office in showing probability of dying This is done by using tables supplied by Dr Stocks [1] showing the probability of not dying of any cause within five years, and a table to correct for expectation of dying from the form of cancer present The authors claim that this method of presenting results is both scientific and exact, and undoubtedly it has advantages For example, for skin cancer the crude survival-rate is only 65% but the corrected rate 82% here the importance of the age factor is seen at once, the crude rate giving a wholly erroneous idea of the results of treatment Another change in this year's report is the substitution of the description of early and late for the four stages previously used. This simple division at once gives the contrast between the results at five years of early and late cases, and makes further tables unnecessary Commentaries on cancers in various sites are intended to interest those with no special knowledge of radiotherapy, who nevertheless want to keep themselves informed of the efforts being made to control cancer The new form of table accompanying each commentary points to the need for earlier diagnosis and to the peak age in each site.

The second part consists of a detailed report, with comparative analysis, of the various techniques employed It presents them in such a form that comparison between methods is possible, enabling radiotherapists to judge the merits of the various techniques and the lines along which progress has been made As full details of the techniques used have already been published,[2] descriptions are restricted to modifications or adjustments In this part of the report the internationally recognised method of classification into four stages is still used, because at present this is the sole means of getting an indication of the comparability of samples, where large groups are being considered For cancers in which the numbers are smaller, division is simply into early and late

During the period under review there has been an increase in the proportion of cases treated with X rays, but radium therapy is advocated by the Manchester school for all cases lending themselves to local application of radium The multiplicity of techniques used in treating cancer of the breast underlines the unsatisfactory position of radiotherapy for this cancer, and no conclusion can be reached on the relative efficacy of different techniques For tumours of the brain, it is thought that X radiation has a part to play, 31% of 187 patients treated having survived five years For cancer of the bladder, gold seed implantation is held to represent an advance on any published methods of treatment For cancer of the ovary the results of radiotherapy represent an improvement on those obtained by surgery Another interesting feature of this part of the report is the number of cases of seminoma referred to the clinic Here there has been a steady increase in number since it became known that even cases with large secondary deposits have a good chance of cure by irradiation

---

[2] Radium Dosage The Manchester System Compiled by W J Meredith Edinburgh 1947

A study of the ten-year results of cases treated in 1934–38 shows that the various types of cancer tend to fall into two groups In one group, which includes cancer of the breast and cancer of the bladder, there is a continuous loss of treated cases, from recurrences, metastases, or persistence of the carcinogenic process In the second group, exemplified by cancer of the uterine cervix, lip, and larynx, if the patient survives five years without recurrence the cure is likely to be maintained Hence during the second half of the ten-year period the prognosis in this group is much better than that of the first group Cancer of the skin and mouth is nearer the second than the first group, so that it now seems possible to say that three out of the four major accessible cancers are curable by competent modern radiotherapy

The report represents the result of much careful work and is a step towards finding an internationally acceptable method of presenting results of cancer treatment, as well as being a clear and restrained statement of what can be achieved by well-planned radiotherapy

Surgery of Cataract

DANIEL B KIRBY, M D, professor of ophthalmology, College of Medicine, New York University Philadelphia and London J B Lippincott 1950 Pp 695 £12

Professor Kirby has undertaken a complete survey of the history, the development, and the modern practice of cataract surgery His book is in five parts, parts I and II covering the development of and preparation for cataract surgery, part III present-day technique, part IV the correction of aphakia, and part V the results For his facts he has searched the writings not only of our own times but of the early Hindus and Chinese, and pictures from early manuscripts are included He has much to say of all the modern types of operation, but naturally pride of place goes to the intracapsular operation and to his own methods of performing it He is a surgeon of great experience, who has given special thought to this branch of ophthalmic surgery, and his observations on modern methods, especially those pages on the mental approach of the surgeon to fine and critical work are particularly valuable His quotations from the writings of those who laid the foundations of modern ophthalmology make fascinating reading Eye surgeons will long be grateful for his presentation of the subject

Bronchoesophagology

CHEVALIER JACKSON, M D, honorary professor of bronchoesophagology, Temple University, Philadelphia, CHEVALIER, L JACKSON, M D, of the same department London W B Saunders 1950 Pp 366 63s

THE authors of this book regard " bronchoesophagology " as " covering a department of study and a branch of medical science ", and indeed it is one which has evolved largely from their extensive and almost unique experience In this work they are not only concerned with the technique and instrumentation required in dealing with the bronchial tree and the œsophagus, but indicate the points at which cooperation with other branches of medicine and surgery are necessary This does much to allay the suspicion that bronchoscopy and œsophagoscopy were becoming isolated from other branches, and that diseases of, or near, these structures were being regarded from too limited a viewpoint In this country bronchoscopy and œsophagoscopy are often routinely handled as part of general thoracic work by both physicians and surgeons, as well as by laryngologists The book is comprehensive, and is very well illustrated in line and photograph There are remarkable sections dealing with foreign bodies in the bronchus and œsophagus, and the vast experience of the authors, covering several thousand cases, is illuminating Each case is studied carefully, and if necessary the foreign body is reproduced and practised on with special forceps—newly designed, if need be This care in itself explains how such a high proportion of successes is achieved. The description of pathological conditions of the bronchial tree is full but less detailed than the section on foreign bodies, and there is possibly some undue emphasis on the value of bronchoscopic measures over those commonly practised by the thoracic surgeon The value of endoscopic treatment of bronchial adenoma can be well appreciated from the account given here If there is an extrabronchial projection of the growth, a final cure by bronchoscopy cannot be expected, but where it presents as a polyp it may well be removed successfully by bronchoscopy, or, indeed, if surgery is contraindicated, the condition may be temporarily relieved The technique of œsophagoscopy is given in detail, and attention is repeatedly drawn to the possible dangers of improper handling of the instrument Perforations are by no means unknown and many fatalities have resulted from this cause The removal of sharp foreign bodies from the œsophagus is also fraught with considerable danger All conceivable manœuvres to prevent any damage on withdrawal of foreign bodies are carefully described and illustrated

The work is well produced and some of the coloured endoscopic illustrations made by the authors are especially good

Types of Diabetes Mellitus and Their Treatment

A R COLWELL, M D, associate professor of medicine, Northwestern University Medical School, Chicago Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 97 16s 6d

THIS is a simply written general account of diabetes for those not already well acquainted with the subject. Professor Colwell deals separately with diabetes of different degrees of severity and gives useful information on diets He treats controversial topics in a disarmingly direct manner, but includes 50 key references to subjects treated summarily in the text Professor Colwell is among the foremost experts on the use of insulin mixtures, and his recommendation to use mixtures prepared previously in sterile ampoules rather than in the syringe at the time of injection could well be taken to heart by many in this country He states clearly that two doses of unmodified insulin are usually incapable of controlling the blood sugar for 24 hours—another fact which needs to be more widely appreciated He advises the use of high ratios of fat to carbohydrate, even when insulin is being taken, this does not conform to recent work relating the development of atheroma to dietary fat, but the matter is still sub judice Once the reader has accepted the term " desugarisation," and realised that the standard technique of the glucose-tolerance test differs from ours he will find that the book is as appropriate for British as for American use

John Ferriar

EDWARD M BROCKBANK, M D, F.R.C.P London Heinemann Medical Books 1950 Pp 51 6s

IN this little book Dr Brockbank has given us a study of a many-sided man, John Ferriar (1761–1815) As physician to the Manchester Infirmary he was the first successfully to organise measures to control the spread and the enormous death-rate of typhus and other fevers His board of health and his fever hospital, called by him hopefully " The House of Recovery," were taken as models in many other cities He was the first, or among the first, to establish the connection between acute rheumatism and heart disease A bibliophil and a poet, his knowledge of literature led to his famous exposition of the sources from which Sterne had culled his *Tristram Shandy* and his *Sentimental Journey*—sources which he used so freely that his admirers have had to change their praise of his originality to applause for the deftness with which he has blended and incorporated the imaginings of others

Sir William Osler, too, was an admirer of Ferriar, and Dr Brockbank has added the story of his visits to Manchester and of his interest in the subject.

THE LANCET

LONDON SATURDAY, MARCH 10, 1951

Industrial Health Services

To any suggestion that the industrial health services are taking doctors and nurses away from their proper work the Dale Committee [1] answers that these services are necessary, that they overlap little with other services, and that what overlapping there is benefits the National Health Service and the output from the factories. As we noted last week, the committee recommends that the development of the services should be encouraged, and proposes the formation of a standing joint advisory committee to coordinate the industrial with the general health services

It seems strange that, at this point in the history of our highly industrialised society, it should be necessary to apologise for the existence of the services which, however inadequately, look after the health of our large industrial population E L COLLIS's remarks made in 1915 about the tardy development of the industrial health services have already been quoted in these columns,[2] but they will bear repetition Referring to GREENHOW's brilliant investigations in the 1860s into the effect of occupational dusts on the lungs, he said

> "Why work so well started was then allowed to lie dormant for so long, while other aspects of public health were being strenuously developed by medical officers of health with inspectors of nuisances appointed for every town and district, reinforced now by a battalion of tuberculosis officers, is astonishing "

There can be no doubt that the local authority public health services, hampered by local politics and influence, lost a great opportunity in the middle of the last century to develop the industrial health services , and it was left to the Factory Department with its certifying surgeons, and a few enlightened factory owners, zealous reformers, and perhaps the trade unions, to carry on the struggle for safer and healthier working conditions in factories Nowadays, on the other hand, many organisations, groups, and Government departments, both local and central, are keen to take industrial medicine under their wings, and the report of the Dale Committee has been eagerly awaited because it was hoped that it would give a strong lead for the future The committee was asked "to consider what measures should be taken by the Government and other parties concerned to ensure that such medical man-power is used to the best advantage," and the outcome is disappointing because the nettles of controversy have not been grasped firmly and the recommendations leave the position nearly unchanged Perhaps because of unresolved differences of opinion within the committee, the lead given is feeble Surely it would have been within the committee's competence to say why the Ministry of Health should or should not take over all health matters including industrial health , to give the reasons for and against the medical officers of health dealing with the subject , to discuss the suitability of the Ministry of Labour, the Ministry of Fuel and Power, or, curiously enough, the Treasury (for evidence was taken from some of its officials) for controlling the services Again, it would have been useful to know what the committee thought about the effect of lay administrators' control over health matters—whether, for instance, it has helped or hindered the development of the industrial health services Refraining even from a summary of the arguments, the report goes out of its way to avoid controversy What is meant, in referring to health services for workers in shops and offices, by the statement that "the proper authorities to encourage the development would, we think, be the authorities respectively responsible for the enforcement of general health standards "[2] It would have been easy to say that the authorities were the Ministry of Health, the medical officers of health, the regional hospital boards, or the Ministry of Labour as it stands, the recommendation is capable of as many interpretations as there are protagonists Another strange sentence is "industrial health services are indeed not wholly medical in character but they are bound up with the carrying out of certain functions, largely non-medical, at the place of work." Why should the industrial health services be singled out in this implication that doctors are not really needed in dealing with all aspects of a health service ? The same can be said about any health service, because doctors are always assisted by non-medical auxiliaries The sentence smacks of the recent development in the United States of the industrial hygienists or "health engineers" who are now maintaining that in order to deal with industrial health it is unnecessary to have a medical qualification

The committee has nevertheless done a valuable work in setting forth clearly the present position of the industrial health services and is emphasising their importance to the nation It shows that about 250 doctors are engaged whole time in factory work, and that there are 1789 appointed factory doctors and 1287 other doctors taking part in factory medical services Also, about 2600 State registered nurses and 1400 other nursing staff are employed in factories Despite the shortage of nurses, the committee believes that they should be used in industry , but they should be used for strictly nursing duties—not, for instance, as welfare officers—and their labour should be diluted as much as possible by giving them subordinate staff As regards dental, ophthalmic, ambulance, and medical auxiliary services, the committee finds that there is no overlapping with similar services for the general public It expresses the opinion that there should eventually be comprehensive provision for occupational health, covering not only industrial establishments, both large and small, but also workers in shops and offices, to which the general health standards of the Factory Acts should be applied. But this development is regarded as remote, and not to be achieved without much more experience to be gathered from future surveys and experiments The drawing up of any national scheme for an industrial health service would also depend on further surveys and experiments All factories are obliged by law to maintain certain standards of healthy environment, and if they employ people in certain processes with special risks, or if they employ young persons at all, they have to consult the appointed factory doctor Services like those established in some of the larger factories might be neither practicable nor appropriate in smaller factories which need some further provision Attention is drawn to the group services for smaller factories at Slough, Bridgend, and Hillington, and the committee would like to see further group experiments made on a scale that the average small employer is willing and able to afford They realise, however, that before health supervision beyond the minimum already provided can be extended, even moderately, there will have to be a big increase in the numbers of doctors and nurses available to industry " Meanwhile, any detailed planning of a nation wide scheme remains largely academic "

---

[1] Report of a Committee of Enquiry on Industrial Health Services Cmd 8170 H M Stationery Office Pp 35 1*s* 3*d*.
The committee was appointed by the Prime Minister on June 1 1949 and its members were Judge E T DALE (chairman) Mr J T BYRNE Dr T A LLOYD DAVIES Miss M M EDWARDS S R N Miss E M GOSLING S R N Sir ROBERT HYDE Dr WALTER JOPE Mr K I JULIAN Dame ANNE LOUGHLIN Mr J R PHEAZEY Dr LLYWELYN ROBERTS Dr A TALBOT ROGERS and Sir GEOFFREY VICKERS

[2] *Lancet* 1945 i 151

The one positive recommendation is that there should be a standing joint advisory committee to coordinate the development of the industrial health services it should be composed of persons appointed by the Ministry of Health and the Ministry of Labour, together with representatives of the Ministry of Fuel and Power, employers, workers, doctors, and nurses , and there should be strong medical representation on it A similar committee should be appointed for Scotland in which the Department of Health for Scotland would take the place of the Ministry of Health The chairmen of these committees should not be drawn from any of the departments represented on them The main function of the committees would be to correlate advice to be afterwards given by departments on major developments affecting industrial health, with special regard to the best use of medical man power Unfortunately, this method of coördination by advisory committees is at best only a half-hearted one, and it would probably have been better to give one department the main responsibility for the development of the services The outcome of the Dale Committee's deliberations really depends on how the Prime Minister deals with the " detailed consideration of the coordinating machinery " If this is not done effectively the Dale report will go down in the history of industrial medicine as another lost opportunity

Veratrum in Hypertension

THE blood pressure of most hypertensive patients can be lowered temporarily by rest and freedom from everyday cares, aided perhaps by venesection or drugs It is in seeking to make the change permanent, with reasonable safety, while avoiding intolerable side-effects, that difficulties arise Moreover, as TURNER [1] has pointed out, high blood-pressure is only one of the manifestations of hypertensive disease Reducing the pressure may not relieve the patient's symptoms, and may be dangerous Such considerations have not deterred clinicians from cautious trials of the potent methonium compounds, which were discussed in our leading article of Feb 17 This week two correspondents indicate that, even with supervision in hospital, administration of such compounds may have a fatal outcome , and on p 549 Dr KAUNTZE and Dr TROUNCE draw attention to the possible advantages of veratrum preparations Veratrum viride is no novelty , it was familiar to our grandfathers as a remedy for hypertension Twenty years ago Dr DOUTHWAITE [2] reported unfavourably on its efficacy in this condition, and for a time its reputation languished , but in 1949 work in America gave a fresh turn to its fortunes

How the veratrum alkaloids exert their hypotensive action is not certain It is agreed, however, that the effect is not sympatholytic According to GOUTIER [3] these drugs act largely by heightening the response of plain muscle to potassium ions WILKINS et al [4] suggest that they act through a " central " mechanism not hitherto recognised, aided perhaps by peripheral vasodilation Thus, it is claimed, they reduce hypertension while largely avoiding the undesirable side effects of the simple vasodilators , and blood pressure can be reduced without impairing the cardiac output or the circulation in the major organs The slowing of the heart which these alkaloids induce, and which is abolished by atropine, is thought by WILKINS and his associates to be due to action on the vagus centres This " prevents the tachycardia and palpitation that ordinarily results from reflexes arising in the aortic and carotid areas when such a lowering of arterial pressure occurs " Apparently, therefore, these compounds can " maintain the patient in a state of circulatory equilibrium but with a lower arterial pressure " There is evidence for this view For instance, after the blood pressure has been significantly depressed by parenteral injection of a veratrum alkaloid, a normal " cold pressor " rise can, according to MEILMAN and KRAYER,[5] be obtained from the new levels WILKINS et al reported that " postural hypotension did not develop following sub-toxic dosage " , but MEILMAN and KRAYER claimed only that the postural response " did not differ much " from that before the preparation was administered The bradycardia, they maintained, is not responsible for the lowered pressure, since this remains low after the pulse has been quickened with atropine

WILKINS and his associates insist that their laboratory work on veratrum viride was done with " the same old drug " But for their clinical trial MEILMAN and KRAYER used a pure ester alkaloid of veratrum, which they called ' Protoveratrine ' KRAYER et al [6] had previously shown experimentally that " not all veratrum alkaloids, but only some of the ester alkaloids " were " capable of eliciting the reflex decrease in blood pressure and heart rate " It has not yet proved possible to administer protoveratrine orally Given intravenously it produced virtually no side effects in doses sufficient to cause a conspicuous fall in pathologically raised blood-pressure Moreover, in a high proportion of cases the fall was accompanied by relief of headache and reversion of flat or inverted T waves in the electrocardiograph The response was evident in about ten minutes and lasted from one to three hours In America several attempts have been made to find a veratrum compound that is both effective and safe when given by mouth. Freis and Stanton [7] studied the effect of a biologically standardised preparation of veratrum in a powder with tetraiodo-pyrrole. Of 34 ambulant hypertensives who received this substance, 30 had a significant fall in blood-pressure and 27 experienced subjective improvement; 13 had toxic reactions. This was encouraging, but Coe and his colleagues [8] have since published a control series in which the effects of oral veratrum were compared with those of similar placebo tablets. Of 25 patients to whom veratrum was administered, only 2 had a significant fall in blood-pressure; 16 noted symptomatic improvement, but similar benefit was reported by 14 out of 23 patients in the control group. Nausea and vomiting proved troublesome; and some way of eliminating these toxic effects will have to be found before a fully effective dosage of veratrum in this form can be given by mouth. In his survey Dr Kauntze has used a potent extract prepared by Stutzman et al.[9] which has been given the proprietary name 'Veriloid.' Stutzman offers a new hypothesis to account for the hypotensive effect of veriloid. Moreover the experience of Dr Kauntze differs somewhat from that of the American workers; for he finds that the low pressures obtained with the extract were not maintained under atropinisation. On the other hand he agrees with the Americans in his observation that there was "no postural change in the blood-pressure comparable with that after the injections of hexamethonium." Moreover there was a sharp response to ephedrine.

If veratrum has an advantage over methonium it would seem to lie in the lesser risk of postural hypotension. In potency, method of dosage, and variability of effect the two forms of treatment seem to have much in common. Neither touches the cause of the disease. Both, if they achieve their object, must threaten the patient with such risks as vascular thrombosis and extrarenal uræmia. The side-effects, too, are evenly balanced. If veratrum is bad for peptic ulceration and can cause vomiting in its own right, at least it does not precipitate bromism, nor "methonium paralytic ileus." In short, both these types of preparation offer encouragement but as yet no fulfilment.

Bacteriophage

There is now a tendency to discard the name "bacteriophage" and to refer collectively to these organisms as the bacterial viruses; for "bacteria-eating" is only one of the properties of the group, and one that occurs principally under experimental conditions in the laboratory. To the microbiologist this group of viruses is at present important not so much because of their ability to destroy bacteria as because they provide a model system in which to study the relationship of a virus with its cell host.

Using the technique described by Fisk [10] it can be shown that many bacteria carry bacteriophage without undergoing lysis; so, unless we believe in spontaneous generation, or in some autocatalytic process in the bacterial cell, it is clear that these viruses are ordinarily in symbiosis with the bacteria. Though itself apparently unaffected, the bacterial strain which carries phage is capable of causing lysis if mixed with a similar bacterial strain. To explain how a strain can carry phage without being attacked by it, two hypotheses are offered. The first is that the bacterial culture consists of two populations, one of which is resistant to the phage while the other is sensitive, and the phage is propagated by multiplication in the sensitive organisms which are derived by mutation from phage-resistant bacteria. The second possibility is that the phage-carrying strains are equivalent to an immune carrier, there being little multiplication until the phage meets a sensitive strain. This second hypothesis finds support in the work of Gratia [11] and others who have shown that phages can be carried by bacterial spores, and then have the same resistance to heat and other agents as the spore. The immune bacterial carrier may have a chemical grouping at its surface to which the phage attaches itself and by which it is prevented from entering the bacterial cell.

Electron-microscope studies have shown that the bacterial viruses vary as much in form as the animal viruses. Ruska,[12] in photographs of *Bacterium coli* bacteriophages, demonstrated variations from tadpole-shaped viruses to small round bodies; the tail, though resembling a flagellum, does not give motility to the virus. Both Wyckoff [13] and Merling,[14] from electron-microscope studies of the reproduction of bacteriophage, have suggested that multiplication is by binary fission; but this has not been confirmed. Doermann [15] has attacked the same problem by mechanically breaking up the bacterial cell after the bacteriophage particle has entered it. Apparently, after the phage enters the cell it loses its identity, and it only reappears shortly before the cell would normally burst to liberate fresh phage particles. (This finding fits in with Hoyle's [16] observation of the appearance of the soluble antigen of influenza virus before the infectious particles appear in chick-embryo cultures.) The lysis of the bacterial cell does not seem to be due to any enzymic action of the phage; nor apparently is it due to the cell becoming full of phage particles, since Cohen [17] has shown that in an oxygen-deficient cell a single phage particle causes immediate lysis—and thereby destroys itself.

An understanding of virus metabolism might give a key to the preparation of compounds which would prevent the intracellular growth of viruses. A step in the right direction is the work of Delbruck [18] and his colleagues in the development of the one-step growth-curve technique, which has shown that after the bacterium is infected there is a latent period before fresh virus is produced; and then, quite suddenly, virus is released from all cells infected at the same time. The increase in phage numbers proceeds by a series of steps, the interval between steps being of the same duration, and characteristic for each bacteriophage, under constant conditions. By using the growth-curve technique Cohen and Anderson[19] have determined the minimum nutritional requirements, in the medium in which the bacteria are grown, for multiplication of the bacteriophage. Working with the T series of coliform bacteriophages, they and others have shown that the material for the synthesis of fresh virus comes not from the bacterial cell but from the medium in which the bacteria are growing, and that for such synthesis the virus depends on the bacterial host's enzyme systems. This might explain Knight's[20] claim to detect antigenic differences in influenza virus according to the host in which it is propagated. It might also explain the specificity of the virus for a particular type of cell.

Work on the genetics of the T series of *Bact. coli* bacteriophages has shown that within this group a large number of recombinations can take place. A notable experiment in this field is that of Luria,[21] who treated two phages with ultraviolet light so that neither could reproduce itself. These two phages were then introduced simultaneously into a single cell and were able to produce fresh phages with the mixed characters of the two parent strains. To explain this successful rejuvenation, Luria[22] has suggested that phage multiplication proceeds by a series of steps. The particle entering the cell breaks up into a number of genetic units, which attach themselves to a host enzyme system and impose their own genetic pattern on it, so that each unit is reproduced a number of times. These units then recombine to give the infective agent. In his ultraviolet-light-treated particles he supposes that the genetic units from one replace those destroyed by ultraviolet irradiation in the other. The essential requirement for successful recombinations is that the cell shall be infected simultaneously with the two types of closely related virus. Probably this condition is seldom fulfilled outside the laboratory, but if such recombination occurs naturally it may give birth to a new strain of virus with epidemic propensities. Certainly in influenza there seems to be a periodic change of antigenic structure in the A strains prevalent throughout the world.

Annotations

PURE FOOD AND NUTRITION

The more disreputable characters in *Candide* were killed off a number of times, but always turned up again as hale as ever, and it is so with abuses. We can never say "That evil is gone for good," for sooner or later it will come sneaking back in some form or another. Thomas Wakley's splendid campaign against the adulteration of food, which Mr. Laurence Dopson recalls on another page, ultimately won for us the Sale of Food and Drugs Act of 1875, but Dr. H. E. Magee, who presided at a conference on Nutrition and the Pure Food Laws held by the Nutrition Society on March 3, noted that chemical substances of increasing complexity are finding their way into food today. Some are innocuous, some beneficial, and the action of some is open to doubt. The preservative regulations are due for revision, and the word "preservative," in particular, as Mr. G. W. Monier Williams, D.SC., pointed out, needs defining afresh. Mr. C. A. Adams, of the Ministry of Food, remarked that food legislation for the protection of the consumer now provides that an article should not be deemed a food merely because it has medical value. Moreover, the descriptive words "not of the nature, substance and quality" have now been changed to "not of the nature, not of the substance, not of the quality"—making three separate offences possible. Under the Defence (Sale of Food) Regulations there are powers for dealing with misleading labels and advertisements, including those in which a true description of the foodstuff is given under a misleading title; and an advisory service to the Ministry has vetted 60,000 food labels since the regulations came into operation in 1943. Mr. Adams mentioned that in the United States a manufacturer has to declare the vitamin content of a foodstuff by giving the proportion of the daily requirement of that vitamin which would be taken in average daily consumption of the food.

The formulation of standards is never easy. In Canada, said Mr. Adams, though trade interests are consulted, recommendations come entirely from Civil Servants; in the U.S.A. there is a public hearing, evidence is published—sometimes to the tune of 15,000 pages—and the standards are based on findings from the evidence. Here, of course, we compromise. A permanent Food Standards Committee, made up of representatives of Government departments, professional and technical experts, and trade advisors, meet in private and hear evidence from all who are likely to be affected by the proposed standard. The committee then report to the Minister of Food, and if they recommend a standard the Minister publishes the report. This gives opportunity for further comments which may lead the committee to amend the report; and finally the standard is adopted. It is a sound procedure, but never takes less than a year. A subcommittee of the Food Standards Committee, studying metallic contamination of foods, has already issued a report on arsenic, and is following it up with reports on lead and other metals; and another subcommittee, under Prof. E. C. Dodds, F.R.S., is already examining the preservative regulations; so the public are much better off than they were in Wakley's day, when the likely adulterants in food included sawdust, lead, chalk and alum, with chicory in the coffee, water in the milk, and sulphuric acid in the vinegar.

A small centenary exhibition in honour of Wakley's campaign was shown at the conference, and included the 1851 volume of this journal, in which the first report of the Lancet Analytical Sanitary Commission appeared, and photographs of pages of *Punch*, where the campaign was supported by Mr. Punch in his "Lectures to Tradesmen."

PORPHYRINS

Porphyrin chemistry is one of a number of complicated biochemical subjects which are invading medicine, often to the discomfiture of the clinician. Its importance, however, is fundamental, both in general biology—since it covers the biogenesis of haems, cytochrome, and chlorophyll—and in clinical practice. The porphyria of lead poisoning is a useful diagnostic sign, while constitutional abnormalities of porphyrin metabolism, though rare, can simulate Addison's disease, Landry's paralysis, an acute abdominal emergency, or a confusional psychosis.

An excellent short account of the porphyrins for clinicians was published by Chandler, Harrison, and Rimington[1] in 1939. Three types of substance are of medical significance, all being composed of four pyrrol units linked in a ring by methene bridges. In proto porphyrin, which is present, united with ferrous iron, in haem, there are two peripheral carboxyl groups, in coproporphyrin there are four, and in uroporphyrin eight There are four possible, and two naturally occurring, isomers of each of these, the protoporphyrin of haem belongs to type III, while the porphyrins excreted in disease normally belong to type I Despite these complications, modern separation methods have made it possible to discover much about the synthesis of porphyrins in the body By the use of labelled nitrogen one can trace their synthesis from glycine, and work is in progress to discover the relation between the abnormal porphyrins of porphyria and poisoning and the normal course of hæmopoiesis

---

[1] Chandler, F. G., Harrison, G. A., Rimington, C. *Brit. med. J.* 1939, ii, 1173.

In the valuable lecture which we publish this week, Professor Watson, who is a pioneer of research on this subject, clinical as well as chemical, describes some clinical aspects of porphyrin chemistry He detects significant differences between the porphyrins of alcoholic and non alcoholic cirrhosis, and outlines the modern theory of porphyrin biogenesis A measure of the complexity of this work is found in the fact that some of Watson's most interesting clinical findings depend on the separation of the two isomers of coproporphyrin [2] This is technically very difficult The fluorescence quenching method of Schwartz, on which these findings are based, has not proved very successful in this country, and search is in progress, so far without result, for a paper chromatographic technique In this field the clinician must wait for the chemist, and he may hope for some fundamental information on cell metabolism, but, while waiting, he can greatly assist research by keeping his eyes open for cases of porphyria, and calling in the biochemist when he finds them A full knowledge of hæmoglobin metabolism would be a big gain to medicine, and porphyrin chemistry is a department in which full-scale cooperation has already brought results It is one more example of the extension of the scope of medicine to cover " pure " scientific subjects of which the doctor should be aware even when he does not attempt to memorise structural formulæ

HEALTH CENTRES

NEWS of the likely establishment of the Manchester University Health Centre [3] is most welcome, even though it reminds us how few of the centres projected and promised so short a time ago are still on the stocks Many local health authorities have secured sites and made plans, but money is no longer forthcoming for most of them Moreover, all too often the prior development of alternative medical services in new communities, or the unwillingness of local practitioners to join in setting up a suggested centre, has compelled the health authority to withdraw from the plans it has made. In fact so many projects have come to nothing that everywhere enthusiasm for health centres is waning, and we are in danger of crying sour grapes, and of persuading ourselves, even before any have been tried, that health centres are things we never really wanted

This would be a pity When the promise of practice from health centres was first made it was received with favour both by the profession and by the public Since then much thought has been given to the problems involved, and much valuable preparatory work has been done While it is true to say that this work has revealed many difficulties to be overcome before the smooth running of health centres can be assured no really insurmountable ones have been encountered, and those that remain are chiefly such as call for practical experiment They provide in fact added reason for the early establishment of experimental centres rather than arguments against their development A generation ago, Lord Dawson's committee gave us a detailed report on health centres, but the value of its work was largely lost because none of the suggestions were translated into action The same will happen now, and the many recent studies will be wasted if their conclusions cannot be put to the test of daily practice in prototype centres The more these prototypes can embrace different types of centre, and different types of community, the more valuable will the experiment prove when the time comes to create better health services than we can afford today

The Manchester centre—if all goes well—is to develop under the auspices of Manchester University with assistance from the Nuffield Provincial Hospitals Trust and the Rockefeller Foundation It is to be housed at Darbishire House, Chorlton-on Medlock, which has latterly been a hostel for business women and students The cost of its purchase and adaptation is being paid by the Nuffield Trust, and the building is being leased to the university at a nominal rent The intention is that the centre shall be developed into a comprehensive health centre, with maternity and child-welfare and school health clinics, together with accommodation for five or six general practitioners and the necessary ancillaries Within two years, as the scheme develops, it is hoped that each of the general practitioners in the centre will be putting in two weekly sessions at one of the clinics, and also two or three sessions as a clinical assistant at one of the local hospitals The practitioners will also help to train students at the university medical school These extra duties will necessarily take a good deal of time, so, though all their present lists exceed 3000, they have agreed with the university that they shall keep their lists in future below 2750 Financially they will not lose thereby, for with the extra remuneration they will receive for their hospital, clinic, and teaching work they should quickly be earning more than they could get from full lists of 4000 Moreover, during the first two years they are to pay nothing for the use of the health centre, and a fund provided by the Rockefeller Foundation guarantees them against any loss of income in the first seven years and assures them of pension rights equivalent to those accruing to a list of 4000 patients Also they can still see private patients in their own home surgeries

Altogether it seems that the doctors have made a good bargain But the total money involved is not excessive, and it will be well spent if used to demonstrate the value of group practice in health centres and the wisdom of enabling suitable general practitioners to help in the training of medical students The disadvantage of the financial arrangements has been that the Ministry of Health has not been able to agree that they really correspond with those it can sanction for health centres under the National Health Services Act To bring the scheme within the terms of the Act the local health authority would have to have acquired or leased the centre and its equipment, from the university, and have accepted responsibility for its maintenance and for the payment of the non medical staff This would have meant an annual charge upon the Manchester City Council of close on £7000, of which half would have been reclaimable from the Ministry of Health As the Ministry is unwilling to recognise the centre for purposes of grant, it is probable that the university will itself need to shoulder this expense, relying on the health authority to instal clinics and to make a voluntary contribution—without Government assistance—towards their maintenance.

In spite of these enforced variations from the expected usual procedure in health centre development, the Manchester experiment should be of real importance But others are needed in addition, and we trust that doctors will henceforth refrain from saying, like those in Sheffield and more recently in Norwich, that it is an excellent idea to try health centres in almost any part of the country save their own. A true pioneering spirit is needed in many more localities than one, if we are to learn how methods of general practice can be improved. As the Collings report urged, there is immediate need for practitioners to form their own groups, without waiting for ideal buildings, and there are also other promising possibilities to be explored, such as the use of diagnostic centres. We are very glad to print this week a letter from the secretary of the Nuffield Trust in which he describes the prototype diagnostic centre to be built at Corby.

STANDARDISATION OF X-RAY FILMS

THE need for a high and uniform standard of X-ray films in cases of suspected pulmonary disease has long been recognised. Lack of agreement among observers as to what is the best type of radiograph, the use of sets of different capacity in different hospitals and clinics, and lack of standardisation of equipment made by different manufacturers, together with errors inherent in such apparatus as time switches and variations in mains supply, all make for difficulty in securing the standardisation needed for accurate diagnosis and assessment of progress. The radiological subcommittee of the Industrial Pulmonary Diseases Committee of the Medical Research Council have been studying the problem and last year published their recommendations. These cover size and identification of film, position of the patient, the control of variables in technique, darkroom procedure, and other points; and the committee also define what is in their opinion a satisfactory first radiograph.

The committee say that much further research into the factors concerned with standardisation of chest films is evidently necessary, and they are planning further investigations. But the recommendations they now make should go far to improve the standard and diminish the variation that exists not only between films taken on different sets but also between films taken on the same set and even of the same patient. Meanwhile the collection of films which they used may be inspected, and sets of standard radiographs can be bought from Miss K. C. Clark, Tavistock House North (First Floor), Tavistock Square, London, W.C.1.

FAVISM

THIS curious hæmolytic disease is a serious hazard in the Mediterranean countries, especially Sardinia. It is connected with broad beans, and is induced either by eating insufficiently cooked beans or, less often, by exposure to the pollen. The anæmia may prove fatal; but, as we indicated three years ago,[1] pathological studies have been few. Cadeddu,[2] however, has recorded 8 fatal cases on which he was able to carry out full post-mortem examinations. The clinical notes show that the red cells were grossly reduced to levels even below 1 million per c.mm., and there was the usual accompanying leucocytosis; hæmoglobinuria and enlargement of the spleen were constant features. The findings were those usual in hæmolytic anæmias whatever the cause, and do not help in determining the ætiology of the disease or in indicating treatment.

The sensitivity to pollen of the broad-bean flower has suggested that the condition may be allergic in origin. Leone,[3] also working in Sardinia, has put this theory to the test by giving anti-histamine drugs to 21 children, varying in age from 12 months to 12 years, who were suffering from favism. They were severe cases, the initial red-cell counts ranging from 770,000 to 2,470,000 per c.mm. Most of them were given pyribenzamine in a total dose of 150–300 mg.; some had 'Antistin' or 'Fargan'. Blood-transfusions were needed in only 6 of the patients. 16 of the children had hæmoglobinuria, which ceased after 1–3 days' treatment; the toxic symptoms—fever, vomiting, diarrhœa, and collapse—were rapidly and strikingly relieved. Leone points out that she had previously recorded increased blood-histamine levels in these cases. From her experience she recommends immediate treatment with pyribenzamine or antistin, 50 mg. daily for 3–6 days; these doses can probably be increased for adults.

The biggest puzzle about favism—its distribution—still remains unsolved. Favism is almost entirely restricted to the Mediterranean area. Its chief focus is Sardinia; but it is also well known in Sicily, Crete, the Ionian isles, and a few small localities in Italy, Greece, and Turkey. Sporadic cases have been reported from France, and 8 in Italians in the U.S.A. Now Pedro Pons and Surinyach[4] report the first 8 cases found in Spain. These were distributed among three families, and seventeen attacks of hæmolysis were recorded. All the members of the first family were natives of Barcelona. In the second family the mother, subject to favism, had a French father and a Catalan mother; the father, a native of Barcelona, did not have favism, but 2 of the 3 sons were affected. The third family came from the Balearic Isles. The geographical distribution of favism led to the theory of a peculiar toxicity of the soil or of certain stocks of vegetables. This theory was disproved by the fact that the subjects of favism are sensitive to all kinds of broad beans from any country, and those who do not get favism are not susceptible to beans grown in Sardinia. The Sardinian workers therefore turned their attention to the condition of the blood in the apparently healthy parents and siblings of the affected children. Boi[5] gives figures showing that increased serum-bilirubin was common; the blood-picture showed an excess of microcytic red cells, and the fragility of the red cells was often increased. These findings support the view, consistently supported in Sardinia, that favism is based on a constitutional peculiarity that is not merely familial but also racial and may be linked with a racial peculiarity of hæmopoiesis.

The Mediterranean area already has one constitutional "Mediterranean anæmia," also known as "thalassæmia" or Cooley's disease. The Spanish report on favism suggests that the abnormality in favism is linked to Mediterranean anæmia. But in fact the results quoted show that they are different. In Mediterranean anæmia the blood-picture is characterised by the appearance of "target cells" (unusually thin and resistant red cells); but Boi's pictures of the blood in patients with favism and their relatives show no target cells, and his figures show an increased fragility more like that seen in congenital spherocytic anæmia. It is of course not improbable that some cases will be found with features of both favism and Cooley's disease. Powell et al.[6] have recently reported a remarkable family of Sicilian ancestry in which the father had sickle-cells, the mother thalassæmia, and the children features of both. Some anthropological studies have been made to see if traces of Cooley's disease, which causes typical skeletal changes, could be found in skeletons of ancient Mediterranean races. Graziosi discovered generalised osteoporosis in a skeleton from the Upper Palæolithic age in Sicily, and interpreted it as due to disease during life. Gatto claimed that the owner of the skeleton belonged to the Palæo-Mediterranean race, in which had arisen the mutation responsible for thalassæmia or Cooley's disease. Maxia and Cossu[7] have examined radiographically 95 skulls of various ages (including Neolithic, Bronze Age, Punico-Roman, and medieval) in the anatomical museum at Cagliari. In only 8 (3 of the Bronze Age and 5 medieval or modern) did they find any slight alterations referable to Cooley's disease. They conclude that the suggestion that Cooley's disease was especially linked with ancient Mediterranean man is far from proved, and that it is not even certain that descendants of that race are to be found in Sicily and Sardinia. In the latter country no skeletal remains or implements of the Upper Palæolithic period have yet been found.

SWIMMING-POOLS

SWIMMING BATHS in Britain date back to Roman times, and Dr. Russell of Brighton first popularised the remedial effects of sea bathing around 1750, but it is only in the last hundred years that local authorities have begun to make provision for indoor bathing, and the modern type of swimming pool is less than 50 years old. Today the demand greatly exceeds the supply, so that in the season overcrowding creates potentially dangerous conditions; the Ministry of Health have therefore revised their memorandum[1] indicating how these dangers may be obviated.

The risk of infection from the water itself is often exaggerated. Gastro-intestinal infections are seldom traced to the swimming pool, and skin infections and conjunctivitis are more likely to be spread by contaminated towels and swimming suits than by contaminated water, though overdosage with chlorine or other chemicals may produce an irritative conjunctivitis and skin rashes. The swimming bath is sometimes blamed for otitis media, but it seems more probable that mechanical pressure from faulty breathing has helped to push infective material along the eustachian tube than that a hæmolytic streptococcal infection has been acquired from the water. As for poliomyelitis, the main dangers associated with bathing are those of too close contact through overcrowding and of susceptibility being increased by over-exertion, for the poliomyelitis virus is readily killed by efficiently chlorinated water. Even during poliomyelitis epidemics the balance of evidence is against the closure of properly controlled public baths and swimming pools.

Most of the Ministry's memorandum deals with the purification of bath water. The old fashioned fill and empty system has given way to the continuous filtration method, fortified by sterilisation (usually with chlorine) and aeration, which, when properly done with modern plant, can keep the water clear and sparkling and its bacterial purity not far from drinking-water standards. For indoor baths the period of complete turnover of the water should not exceed 4 hours, and the rate of filtration through the sand filters should be about 200 gallons per square foot per hour. The use of a coagulant, such as an aluminium salt, helps to clarify the water, which for this purpose should be kept slightly alkaline (pH 7·2–8·0), if necessary by adding soda ash or lime. The sterilisation of swimming-pools by chlorination has advanced in the last few years. Chlorine gas is the best form of chlorine to use, because the dosage can easily and accurately be controlled to meet varying demands; and instead of the older marginal chlorination method with a free residual chlorine concentration of 0·2–0·5 p.p.m., or the use of slower acting chloramines, break-point chlorination is now being widely adopted. When chlorine is added to water containing ammonia, chloramines are formed, but in the presence of an excess of chlorine these break down to form hydrochloric acid and nitrogen. During this process the addition of chlorine causes a fall in the total residual chlorine, but when the "break point" has passed there is a rise in the free residual chlorine, which is much more rapidly bactericidal than chloramine. Break-point chlorination requires more chlorine and closer supervision than the older methods, but levels around 1–2 p.p.m. are readily tolerated and give a wide margin of safety. The memorandum describes the tests for free and combined residual chlorine with orthotolidine and other agents, and it suggests that, provided the chlorine concentration is tested at least three times a day, there is little need for bacteriological control, though occasional checks against the chemical tests seem useful.

More attention should be paid to the risks of infection and contamination outside the actual swimming pool. Hot showers and foot baths should be provided, to encourage bathers to wash before entering the pool. The margins should be wide, sloping gently away from the pool, and the dressing boxes should if possible be placed so that the bathers need not walk on the margins before they undress. Communal costumes and towels must be properly washed and sterilised. The dressing boxes should be well lit and ventilated, and easily cleaned and disinfected, and the lavatory accommodation should be ample. The bath superintendent, who is mainly responsible for maintaining hygienic conditions, should enter in a log book the number of bathers admitted every hour; the alkalinity, clarity, and chlorine content of the water; and the essential data about the performance of the filtration and sterilising plants.—And now, let us pray for a warm summer!

TUBERCULOSIS A PRESCRIBED DISEASE

REGULATIONS have been made, under the Industrial Injuries Act of 1946, to prescribe tuberculosis as an industrial disease[1] for nurses and others who contract the disease as the result of close and frequent contact with the infection in the course of their occupations. It is interesting to reflect that, as far as nurses are concerned, this course would never have been necessary if all hospitals had been as thorough as the best in their care of their nurses' health, and of the welfare of those who, in spite of precautions, acquired tuberculosis in the course of their duties. The scheme came into force on March 1, and a leaflet[2] explaining its provisions clearly and fully is now being distributed by the Ministry of National Insurance. Those entitled to benefit by the new regulations must, at some time since July 4, 1948, have been in close and frequent contact with some source of tuberculosis infection, either when nursing or treating medically one or more people suffering from tuberculosis, or giving ancillary service as a ward-maid, laundry worker, health visitor, or home help; or as a research worker engaged in research in connection with tuberculosis; or as a pathologist, laboratory worker, or post-mortem attendant dealing with tuberculous material, or in an occupation ancillary to these. To benefit, the worker must be suffering from tuberculosis, not necessarily of the lungs, and the infection must be due to the nature of her or his work in one of the occupations described. The benefits are the same as for accidents at work, and the leaflet tells the patient how to claim for them.

It is as well that this question is finally settled. While it was still possible to argue over the degree of risk to which nurses and others are exposed, there were bound to be inequalities, both in the precautions taken to protect them, and in the amount of responsibility accepted for those who acquired a tuberculous infection. Now it becomes a matter of duty for all hospitals to protect their nurses as far as possible, and to do all they can to ensure their recovery and reablement.

THE INDEX and title-page to Vol. II, 1950, which was completed with THE LANCET of December 30, is now in preparation. A copy will be sent gratis to subscribers on receipt of a postcard addressed to the Manager of THE LANCET, 7, Adam Street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

CURRENT ADVANCES IN THE STUDY OF PHYSIQUE

PHOTOGRAMMETRIC ANTHROPOMETRY AND AN ANDROGYNY SCALE *

J M TANNER
M B Lond , M D Penna, D P M
LECTURER IN PHYSIOLOGY, ST THOMAS'S HOSPITAL MEDICAL SCHOOL, LONDON

THAT some relations between physical build and behaviour exist in both normal and psychotic people is well known and requires little comment It is obvious enough to those who do not completely deny the validity of observations made in the field, but it is obvious only in its general, more anecdotal, aspect To particularise and clarify the relations demands many life times of careful, meticulous measurement, and the exact and understanding application of scientific method

In the last 10–15 years two new and more powerful techniques for the assessment of physique have been evolved and I wish to devote the first part of this paper to reviewing the more important results achieved by their use in relation to temperament, psychosis, and neurotic behaviour The latter two parts are concerned with the work of my own laboratory, first in developing the technique of *photogrammetric anthropometry*, as the measurement of individuals by means of photography is called, and secondly in constructing a new, and as I hope more powerful, measure of *androgyny*, or the degree of femininity of build in the male

I Physique, Psychosis, and Neurosis

The two recent classifications of physique I refer to are those of Sheldon (1940), known as *somatotyping*, and the *factor analysis* classification largely developed by Burt (1947) and Burt and Banks (1947) Both are by now too well known to warrant a long description here, and the situation has not materially changed since 1947, when on a similar occasion I discussed their relationships (Tanner 1947)

PHYSIQUE AND TEMPERAMENT IN THE NORMAL

Sheldon and Stevens in 1942 described a rating scale for assessment of temperament, and three components of temperament (viscerotonia, somatotonia, and cerebrotonia), which they alleged were closely related to the three components of physique—endomorphy, mesomorphy, and ectomorphy This caused a good deal of discussion, occasionally acrimonious, perhaps largely because the relationship was described as closer than previous workers had made out, and it was described in more detail and with considerably greater force There was, after all, nothing startlingly new in the idea, Kretschmer's work in particular had accustomed the present generation to it, and before him there were very many others In the face of this discussion, however, it was of first rate importance that some other investigator should try to confirm or repudiate the finding of Sheldon and Stevens, using the same methods for classifying physique and temperament Such a study was forthcoming (Seltzer et al 1948), along with much other highly important material, from the investigators associated with the Grant study of Harvard University, which is a continuing study of a group of healthy normal students during their time at college and in their subsequent careers (Heath et al 1946) A mass of data on the personality of these persons was available from the files of the staff psychiatrists, and 260 persons were classified temperamentally as evenly balanced or predominantly viscerotonic, somatotonic, or cerebrotonic by one of the investigators, McTernan, while another, Seltzer, somatotyped them, neither had any idea of the data of the other The report deals with only one aspect of the alleged physique temperament relationship, the association of dominant cerebrotonia with dominant ectomorphy in physique There were 50 persons whose dominant component of physique was ectomorphy, 42 of these were also predominantly cerebrotonic, and a further 6 showed evenly balanced components of temperament This well marked association between ectomorphy and cerebrotonia is highly significant statistically and, so far as it goes, bears out Sheldon's contention completely It is less quantitative than his investigation, however, and obviously this field could absorb the attention of large numbers of workers for a long time From the same material important studies have been published by Seltzer on the relationship of androgyny of physique to personality and the choice of career (Seltzer 1945) and of bodily disproportions to certain traits of behaviour (Seltzer 1946)

PHYSIQUE AND PSYCHOSIS

Little has yet been published on the relation of somatotype and psychosis Undoubtedly the most important event in this field is the publication of Sheldon's third volume in the Constitution Research Project series (Sheldon 1949) He concludes that manic depressives are, by and large, ectopenes—i e, people very low in ectomorphy (the other two components both being high but in varying proportions)—paranoid schizophrenics tend to be high in mesomorphy, and hebephrenic schizophrenics relatively high in ectomorphy These findings bear out exactly those of Kretschmer for the manic depressives and hebephrenes (Kretschmer's pyknic being an ectopene in Sheldon's terminology)

Kallman (1948) states that among schizophrenics the prognosis varies with the somatotype, the more ectomorphic the worse the prognosis, the more mesomorphic the better the prognosis, and endomorphy is irrelevant

There have been two reports on psychotics in which the factor analysis classification was used Cohen (1940) found differences, of the expected sort, between schizophrenics and manic depressives, and Moore and Hsu (1946) published a Thurstone type factor analysis of Connolly's measurements on 100 psychotics

An excellent bibliography of the pre 1940 literature on physique and schizophrenics will be found in Betz (1942), and the brilliant monograph of Wertheimer and Hesketh (1926) still remains a classic in the field Disappointingly little has yet been done on the two perhaps most fruitful aspects of physique in schizophrenia—androgyny and dysplasia—in both of which schizophrenics seem probably to be abnormally high Perhaps this is because both are difficult to measure, particularly dysplasia There are very few somatotypers skilled enough to obtain valid ratings of dysplasia by Sheldon's method, even if their over all somatotypes are accurate We badly need a metric technique for this

PHYSIQUE AND NEUROSIS

That there is a relation between physique and type of psychosis has been clear for a long time, whether this is also true of neurosis is perhaps more debatable but evidence is accumulating in favour of the idea Excepting Sheldon's (1949) work on delinquents there seems to have been little done in the somatotype field, apart from a study by Tanner and Jones (1948) on repatriated prisoners of war Rees and Eysenck (1945) carried out a factor analysis study of Army neurotics—i e , persons who had broken down under the stress of Army existence —and Rees (1945) has reported a difference in physique between neurotics who complain primarily of effort syndrome and a group of normal Army controls The situation regarding neurosis is not at all clear Hysterics seem to be lacking in ectomorphy, and persons with chronic effort syndrome are excessively androgynous Possibly neurotics as a whole tend to be more ectomorphic, more androgynous, and more dysplastic than the rest of the population, but none of these things has been shown to be certainly true We need more refined techniques both for classifying neurotic reactions and for studying these aspects of bodily build

---

* Abridged from an address delivered to the Royal Medico Psychological Association, May, 1950

II Photogrammetric Anthropometry

Each of the two modern methods of classifying physique starts from different fundamental observations on the person Somatotyping begins with a carefully and specially posed photograph The somatotype is rated *from protracted inspection of the picture and a comparison of it with a key file of pictures of known somatotypes* Sheldon s system fundamentally rests on anthroposcopy—i e , looking at the person Admittedly he later measured his pictures and thus produced a set of tables by which he claimed it was possible to somatotype quite objectively young men between the ages of 16 and 20 in a normal stage of nutrition and health (with the exception of an occasional tie between two somatotypes) Though ten years have elapsed since the publication of these tables there has been not a single report, so far as I know, of any attempt by other laboratories to use this anthropometric technique Perhaps this is because the technique is certainly arduous and time consuming, but it may also be that investigators have met unexpected difficulties Certainly we have, for several years in my laboratory we have been trying to use this metric technique and we have encountered considerable trouble

First, Sheldon gives insufficient details of the photographic technique he adopted for it to be repeated exactly A cardinal point is the exact distance of the camera from the person, and even more so the exact distance of the person's heels from the centre of rotation of the turn table on which he stands, since on rotation from front to back view he comes closer to the camera by an amount depending on this distance This is important because a measurement on the picture depends not only on the corresponding measurement of the man himself, but also on how close to the camera the particular dimension measured is This is called the parallax error, all dimensions have to be reduced to a standard camera centre of rotation of turn table distance

Personal communication dispelled these difficulties, but we then found others For example, the tables do not give unequivocal regional somatotypes when used objectively without a preliminary scopic estimate, thus, in the abdomen the regional somatotypes 263, 353, 433, 443, and 444 all have the same measurements, one cannot distinguish between them Also we consistently get lower readings for ankle diameters than the tables lead one to expect, either British students have slenderer ankles—though not wrists—than American students, or else some snag of turn table distances or, possibly, camera lens errors (the commonest of which tend to be of a type that spreads the image at the north and south poles) may be involved

I say all this not in criticism of somatotyping, which I believe to be the greatest single advance yet made in the study of human physique, but to indicate that in

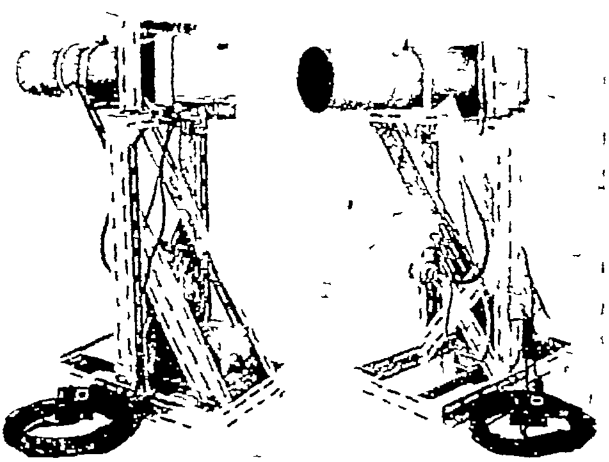

Fig 1—Aerial mapping camera adapted for photogrammetric anthropometry the camera is detachable from the stand and both are very easily portable.

Sheldon's *system measurement is a secondary considera tion* He has now made this very clear himself (Sheldon 1949)

For factor analysis, on the contrary, it is measurement that is all important Using, as a rule, the classical measurements of the physical anthropologist, the factorer can—indeed must—approach the classification of a person carefully blindfolded This, to my mind, is not very satisfactory Factor analysis has its own subjectivities, just as somatotyping has, they reside in the initial choice of measurements for use in the battery, and in the choice of the factor technique of rotation and so forth used after the measurements are intercorrelated Above all, one has the difficulty of reconstructing any kind of mental image of the subject from a set of, say, a dozen factor estimates This is an old difficulty well known to all physical anthropologists who have interested themselves in constitutional research, one has a mass of measurements on a man, but what on earth did he look like ? To answer some questions one may not need to know this, but to answer others and, above all, to think of new questions to ask, an image of the man is a very great help

It was thus perfectly obvious that what was needed was a combination of the two techniques, and it required only a tidying up of Sheldon's photographic technique to secure it The method known as *photogrammetric*

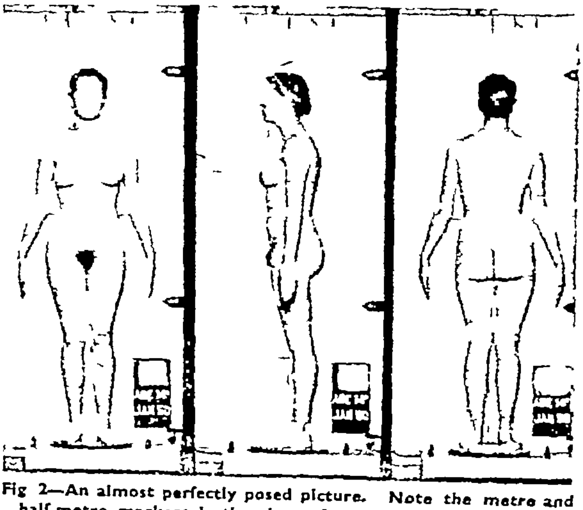

Fig 2—An almost perfectly posed picture. Note the metre and half metre markers in the plane of rotation of the turn-table.

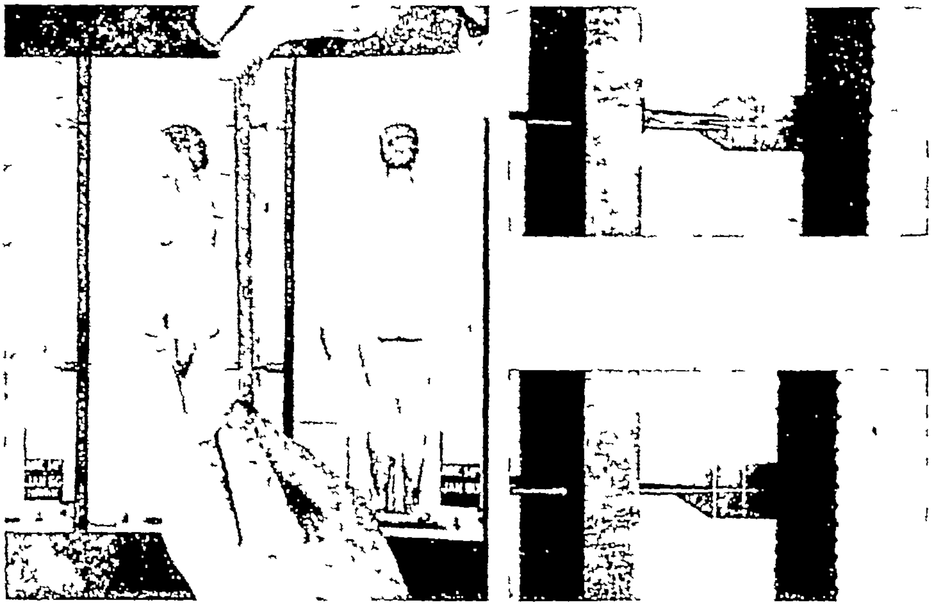

Fig. 3—Testing the enlargement for accuracy. The right hand picture shows enlargements of the pointers seen in the left hand picture.

anthropometry involves taking pictures which not only meet all the requirements for somatotyping but also allow large numbers of measurements to be taken from the photographic image simply and expeditiously. An associated desideratum was that large numbers of people should be handled in a short time, since a good deal of this type of work involves surveys where the persons' time for attendance is limited by industrial or educational considerations.

The details of the technique have been discussed elsewhere (Tanner 1949a, Tanner and Weiner 1949, Dupertuis and Tanner 1950); we use a 10 metre distance from camera to centre of turn table, which reduces the parallax error to under 1% even in extreme cases, and a 10 cm. heel centre of turn-table distance. At first we used a 'Leica' camera with the 'Hektor' 13.5 cm. lens, but we soon found that the only practicable way of getting accurate measurements was off fairly big enlargements, and those from the Leica had too much grain. At the independent suggestion of Mr. N. M. Richards, of the photographic and reproductions branch of the Air Ministry, and Dr. Brian Stanford, we changed to the F. or K. 24 aerial mapping camera, which we have found far more satisfactory.

The camera, fitted with a 20 in. focal length lens, is illustrated in fig. 1. It holds 50 ft. of 5½ in. wide film and usually takes 5 in. × 5 in. square pictures; but we alter it to wind on only a half or a third of this amount, so that we can get front, side, and back photographs of up to 50 people before changing the magazine, which in any case takes only a minute. Enlargements are made from these negatives to exact scale, as indicated by two sets of white crosses on the black pointers seen in fig. 2—one 1.0 metre apart vertically, the other 0.5 metre apart horizontally—which are brought up on the enlargement to 120 cm. and 60 cm. respectively, our allowable limits on the former being 119.6 to 120.4 cm. and on the latter 59.8 and 60.2 cm., inclusive.

The testing procedure is seen in fig. 3. Waterproof base paper must be used, which does not shrink like ordinary material. The pointers are fixed permanently to the turn-table in the vertical plane of its centre of rotation, so that no error in placing them can arise. The background behind the person is illuminated fairly strongly to obviate all shadow, and a grid of horizontal and vertical wires, spaced as shown in fig. 2, is put about 0.5 metre behind the turn-table centre; we find it very useful when taking horizontal and vertical measurements and as a background for studies of growth in children. The best lighting is by condenser discharge flash, using either a single central source, or, rather better, two sources angled at about 30° on either side of the person. Everything is made automatic in these cameras, so that one merely presses a button and the light is flashed, the picture taken, and the film wound on ready for the next exposure.

The measurements, which are largely those of Sheldon, we take from the enlargements at the rate of 40-60 an hour by special pointed proportionately magnifying callipers (fig. 4); the scale reads directly in 0.1 mm. and is × 5, so that 0.1 mm. on the print is 0.5 mm. on the scale. The reliability of

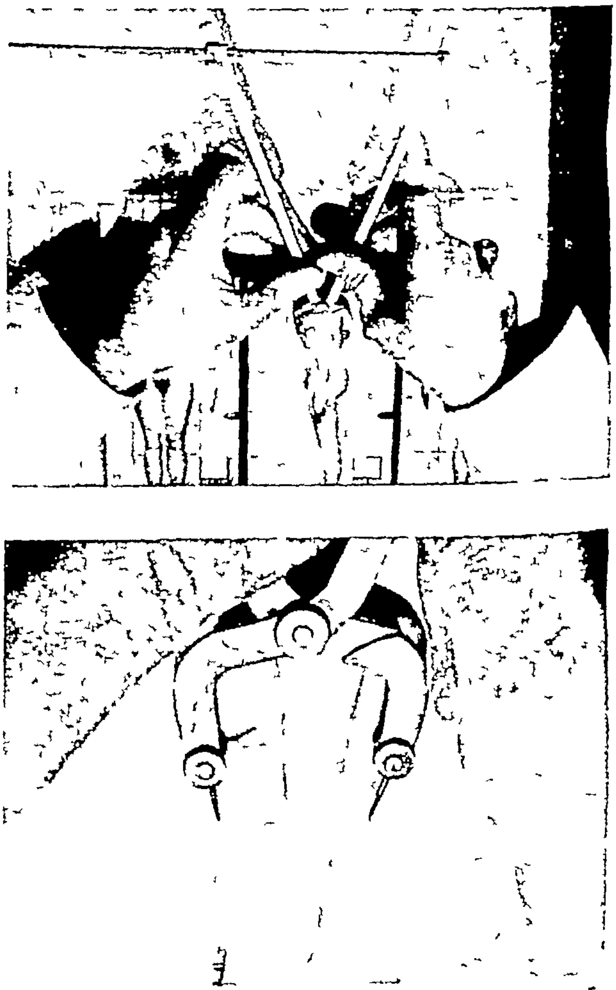

Fig. 4—Measuring the photographs. The callipers give a × 5 enlargement.

this whole procedure has been extensively investigated (Tanner and Weiner 1949) and found to be as good as, or in some dimensions perhaps a trifle better than, that of the classical antropometric measurements. By far the largest error comes in the exact posing of the person, and for this reason Dupertuis and Tanner (1950) have given a detailed description of a pose (fig. 2) which we hope will be adopted as standard for all somatotyping and photogrammetric anthropometry.

We do not eliminate from our routine all the classical measurements just because we want also a photograph and a lot of additional information the classical techniques cannot give us. We routinely take stature, sitting height, weight, biacromial diameter, bicondylar diameters of humerus and femur, four subcutaneous tissue measurements, and others as circumstances dictate. With two investigators and a recorder in the measuring team, the person's time of attendance is 5–10 minutes.

Much valuable material could be collected by interested doctors who are not and do not intend to become expert somatotypers or physical anthropologists. Particularly in hospitals the labour involved would be small in relation to the knowledge resulting therefrom. The technique described here was specifically evolved to meet such needs, once the camera and turn table have been placed in position, all is automatic. Commercial firms will process and enlarge the pictures, and research-workers are eager and willing to help with somatotyping and measuring, if the investigator does not wish to do it himself. All that the photographer need do is spend a day learning carefully how to pose his subjects—this is a necessary qualification. If many outpatient departments and mental hospitals collaborated in such an enterprise, we would soon have a considerable body of knowledge on the physiques of patients with various diseases. If the reader thinks this would be time wasted, let him look at the distribution of somatotypes of cancer patients (Sheldon 1949).

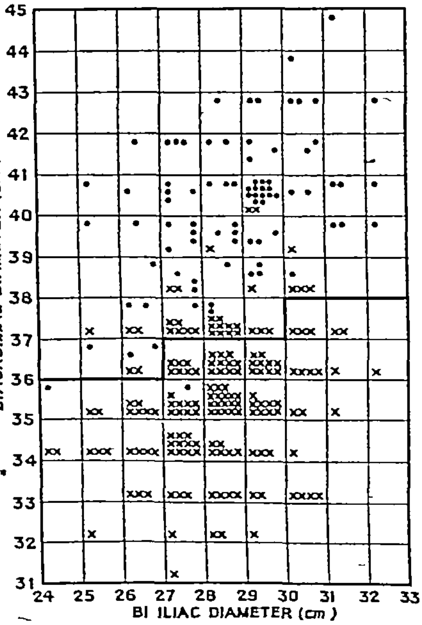

Fig. 5—Discrimination of male and female students by hip and shoulder breadths: circles males, crosses females; equation of heavy line 3 biacromial — bi iliac — 82 = 0.

III. Discriminant Function Scale for Androgyny

For a long time physical anthropologists have used the ratio bi iliac diameter/biacromial diameter as a rough measure of androgyny, on the grounds that these are the two measurements which, relatively speaking, differentiate most the two sexes. Granted the premises, however, it by no means follows that this ratio is the best method of combining the two measurements; in fact, it is certainly not so. There is a statistical method available for finding the best combination, which is called a *discriminant function*, since it provides the best possible discrimination between males and females for any particular combination of measurements. The discriminant function is a line—and in the case of the present data a straight line—which separates the sexes so that those individuals who are one side of it are males, those the other side females. The line may not completely separate the sexes if the original measurements overlap in their distributions, but it separates them better than any other combination of the measurements would; that is, it misclassifies the minimum number of people. Fig. 5 shows the line which best separates a group of male and female Oxford students according to their biacromial and bi iliac diameters. I am indebted to Dr. R. W. Parnell for the data on which this figure was constructed, which comes from a study we are making together on students at the Institute of Social Medicine at Oxford. It can be seen that a fair degree of separation has been achieved.

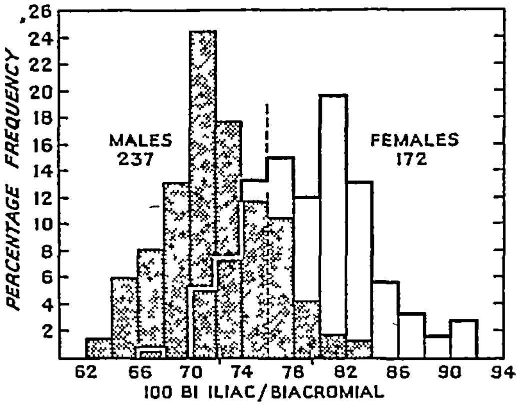

Fig. 6—Distribution of bi iliac/biacromial ratio for male and female students. Interrupted vertical line is line of separation; misclassification totals 21%.

This is a considerably better separation than that obtained by the use of the 100 bi iliac/biacromial ratio. The figure for the ratio which best separates the sexes in this group is 76, and this leaves 42 out of 237 males (18%) the wrong side and 46 out of 172 (27%) females, a total misclassified of 88. This is illustrated in fig. 6.

The best straight line discriminant is approximately 3 biacromial — bi iliac — 82 = 0, and this misclassifies only 14 out of 237 (6%) males and 34 out of 172 (20%) females, a total of 48.

This search for a metric distinction between males and females by a discriminating function may seem somewhat pointless, and peculiarly suited to the academic mind; the practical man tends to use other, to him more familiar, methods. I would agree, were it not possible, perhaps,

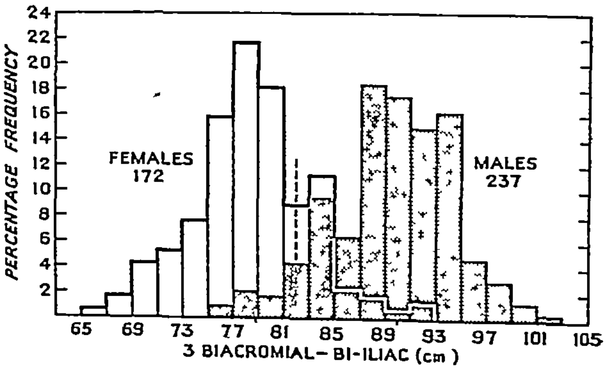

Fig. 7—Distribution of androgyny score for male and female students: interrupted vertical line is discriminant line; misclassification totals 12%.

to use this function as a basis for an androgyny scale It seems reasonable to suppose that the best measure of androgyny which uses these two measurements would be given by a person's distance away from the discriminating line, which would be simply his score on the equation 3 *biacromial — bi iliac* diameter (the 82 being immaterial in this regard) The distribution of these scores for males and females with the discriminating line between is shown in fig 7, the means and standard deviations for males and females are 90 1 and 4 73, and 78 9 and 4 57 respectively It will be seen how much less overlap there is between the two distributions than in fig 6 The argument seems to be if a given person's score is 82—i e, falls on the dotted line—we cannot say at all whether the person is male or female If, however, the score is 95, the probability of the person's being a male is high, and if 75, relatively low A glance at the genitalia would tell us, but the point is that we are classifying as though the genitalia did not exist, or as though the genitalia were themselves misclassifying the individual, because what we are after is the degree of femininity of a male irrespective of the type of genitalia The last part of the argument is that, as the probability of being a biacromial bi iliac female increases in persons whose genitalia allege maleness, the degree of androgyny as we understand the word increases This last phrase contains an operational definition of androgyny, and, unless one granted that the method of measuring androgyny defines the concept, the argument stated above would, I think, be hard to sustain There is no doubt that this scale and the anthroposcopic estimate of androgyny or, as Sheldon calls it, gynandromorphy measure the same feature in human build, but it seems likely that the nature of the two scales will not be entirely similar On the discriminant function scale the distribution of males and females is approximately Gaussian, whereas on Sheldon's scale it is rather heavily skewed Possibly the discriminant has the biometrical advantage here, but I would hesitate to claim a biological one also Whatever the validity of the main argument, however, the discriminant androgyny score is a better scale than the bi iliac/biacromial ratio, which uses the same argument and is both biased and inefficient into the bargain

We could increase the efficiency of our discriminant function by including more measurements, at the same time bringing it to measure with more validity what the rater can so obviously see If leg length, in the form of subischial length (stature minus sitting height) is added, the best discriminatory straight line is then approximately

$$2\ \text{biacromial} + 0\ 53\ \text{subischial} - 1\ 25\ \text{bi iliac} - 81 = 0,$$

and it does improve our discrimination considerably Now only 10 men and 24 women remain misclassified, a total of 34 as opposed to 48 using biacromial and bi iliac only and 88 using the bi iliac/biacromial ratio The mean figures on this better androgyny scale (ignoring the constant 81) are 87 9 for men and 76 8 for women, with standard deviations of 4 07 and 3 95 respectively The best way to improve the scale further would undoubtedly be to use photogrammetric dimensions, because the next best discriminating part of the body is the pattern seen between the legs when the heels are together, or a fixed distance apart, and this is only easily measurable on the photograph However, we have not yet got enough photogrammetric pictures of women to complete such a study

The use of the scale may be illustrated by a single example Rees (1945), who measured 200 patients with effort syndrome and 100 normal soldiers as controls, concluded that patients with effort syndrome were more linear or leptosomic than the controls His data, however, make this conclusion somewhat questionable, he did not use a regular regression equation such as that of Burt and Banks (1947) for the estimate of leptosomic factor, but an index 100 stature/6 transverse chest diameter I have indicated at length elsewhere (Tanner 1949b) the sort of difficulties in which ratios like this sometimes involve one, I think they should be dropped from the anthropologist's armamentarium Though I cannot tell whether or not any of these difficulties arise in the present case, Burt's regression score for leptosomic factor does not differ significantly for Rees's two groups So the question of a difference in linearity had perhaps better be held sub judice for a while What is far more striking in Rees's data, however, are the large hips, narrow shoulders, and short legs of the patients with effort syndrome—the main indication seems to be of a difference in androgyny On the 3 *biacromial — bi iliac* scale the 100 controls have a mean value of 89 8, which is indistinguishable from the mean for the 237 Oxford students, 90 1 The mean for 100 of Rees's patients with effort syndrome is, however, 84 1, and the difference of 5 7 units from the controls is undoubtedly very highly significant statistically, assuming any reasonable figure for the standard deviation of the patients with effort syndrome Indeed, fig 7 shows that only 15% of Oxford students are as androgynous as this mean figure for the patients with effort syndrome, and the difference between controls' and patients' means in relation to the standard error is almost certainly considerably higher than any one derived from Rees's single measurement or index comparisons The conception that these patients with effort syndrome were more androgynous than the normals also makes sense physiologically It is known that the higher the androgyny the worse is the exercise tolerance in normal men, both trained and untrained (Seltzer and Brouha 1943), and that women have a higher blood lactate level after a standard exercise than have men (Metheny et al 1942) Patients with chronic effort syndrome have been shown by Jones and Scarisbrick (1946) to resemble androgynous men in these physiological ways, having low effort tolerances and a high blood lactate level after standard exercise, their blood lactate level, indeed, lies somewhere between that of normal men and that of normal women

It remains to be seen finally, whether this androgyny scale will remain useful in relation to physiological investigations of physique and of the growth of children For it is from these directions that I believe the next major advances in the study of physique will come

Summary

Recent work relating physique and temperament in healthy young men, physique and type of psychosis in psychotics, and physique and types of neurosis is discussed briefly

The technique of measuring people photographically known as photogrammetric anthropometry is described

A new scale for measuring androgyny, or femininity of build in the male and masculinity of build in the female, is described It is founded on the use of a discriminant function obtained from measurements on male and female Oxford students, and the androgyny score is 3 biacromial diameter — bi iliac diameter when only these two measurements are used A better score is obtained using leg length in addition The discriminant line separates males and females much better than does the bi iliac/biacromial ratio, and an example of the use of the scale in medical work is given, showing patients with effort syndrome to be more androgynous than normal controls

Besides my debt to Dr Parnell for the measurements of Oxford students, I wish to acknowledge the continuous support

and encouragement of Prof Henry Barcroft, and the skilled and indispensable assistance of Mr R H Whitehouse, to whom I owe many points of technique I wish to acknowledge also the William Hyde Award of the Research Board for the Correlation of Medical Science and Physical Education, which helped defray expenses

GENERAL MEDICAL COUNCIL

FEB 27 TO MARCH 2

THE General Medical Council held an extra session last week, when the new Medical Disciplinary Committee also met for the first time

Five new members were introduced to Prof David Campbell, the president, and took their seats Dr H Seaward Morley, Miss Florence Horsbrugh, C.B E, M P, and Mr J B Hynd, M.P, are Privy Council nominees, and Prof J H Biggart, C B E, and Prof. A P Thomson represent respectively the Queen's University, Belfast, and the University of Birmingham Miss Horsbrugh, who is an honorary fellow of the Royal College of Surgeons of Edinburgh, is the second woman to take her seat on the council.

DISCIPLINARY CASES

Frederic Syson registered as of 52, Station Road Horsforth, Leeds, M B Glasg (1925) appeared on a charge of having been convicted at Leeds in May, 1950, of incurring a debt of £3 15*s* so obtaining credit by fraud In May, 1949 the council had postponed judgment for one year after they had found him to have been convicted of two charges of drunkenness and two of embezzling in 1945 Dr Syson stated that at the time of the offence he had been in poor health and had taken phenobarbitone He now knew he had a chronic renal condition which interrupted elimination of the drug He was not aware of the offence until he was informed of it after he had been admitted to hospital The President announced that the council found the conviction proved, but to give Dr Syson further opportunity of regaining his position they had postponed judgment until their first session in 1952

Roger St Aubyn, registered as of 18, Redcliffe Square London, S.W 10 M.R C S (1946), was charged with having been convicted at West London magistrates court on June 16 1949, of driving a car while under the influence of drink, and of having been convicted of a similar offence on Sept 21, 1950 The council found the convictions proved but postponed judgment until their first session in 1952

The council directed the Registrar to remove from the Register the name of *Nigel Harold Maurice Russell Monro*, registered as of 442, Nell Gwynn House, Sloane Avenue, London, S W 3, M.R.C S (1936), who had been convicted on Jan 18, 1951, of two charges of procuring morphine when he was not authorised to do so

The President announced that the Registrar had been directed to erase from the Register the name of *Michal Mateusz Torpor Matuszewski*, M.B Polish School of Medicine (1949), provisionally registered, under the Medical Practitioners and Pharmacists Act, 1947, as of 40, Marchmont Crescent, Edinburgh, 9 The case was held in camera

Ram Kissoon Nandlal, registered as of 75, Green Lane, Small Heath, Birmingham L.M S.S.A (1930) appeared before the council charged with having committed adultery with a married woman patient The complainant was the woman's husband, who was represented by Mr E G A Beresford, instructed by Mr T S Walker, solicitor Dr Nandlal, who was represented by Mr Norman Richards, instructed by Messrs Le Brasseur and Oakley on behalf of the Medical Protection Society, denied the allegation After a hearing lasting three days, the council found the facts alleged against him proved to their satisfaction The Registrar was directed to erase his name from the Register

COMMITTEES

At the end of this case, the president said that this was the last penal case which the whole council would hear The council took their first penal case in the Royal College of Surgeons of England on August 11, 1859 "The end of the case of Nandlal," remarked Professor Campbell, "is the end of an era"

The council appointed the first Medical Disciplinary Committee, which held its first meeting in camera at the end of the session It did not consider any cases Because of the impending election the first committee will hold office only until April 28, 1951 The following were appointed

The president, ex officio *England and Wales* Prof R J Brocklehurst D M, Dr J A Brown, Dr O C Carter Sir Henry Cohen, F R C.P, Dr Guy Dain, Prof R B Green, F R.C S Dr E A. Gregg, Dr J P Hedley, Lord Nathan, and Mr N E Waterfield, F.R C.S *Scotland* Dr R W Craig, Sir Andrew Davidson, M.D, Miss Florence Horsbrugh, M.P, Sir Sydney Smith, M.D Sir Henry Wade F R C S.E *Ireland* Dr James Boyd, Dr Frank Kane, Mr R A Stoney, F R C.S.E

The council approved alterations in the standing orders to give effect to its previous decision to abolish the public health, examination, and education committees

---

' the immigration authorities regard successful migrants brought into this country from overseas as being equal to an asset to the country of £10 000 per head Judged by this basis for calculation it will be seen that the equivalent loss to the State as a result of deaths from causes which could and should be prevented will reach colossal proportions—for example road deaths alone in Australia account for a loss of 6400 multiplied by £10 000 or the equivalent of £64,000,000 for the five year period, or approximately £13,000 000 per annum In our own State measures to cope with this problem, serious as it is, have surely been started at the wrong end It is entirely the wrong approach when the Government through the Hospitals and Charities Commission has planned to build large accident blocks at two of the largest general hospitals in the city to cope with the increasing number of people injured in road accidents As I have often mentioned, almost all these casualties are preventible, and the enormous outlay for such hospital buildings and the staff to service them—even if available—could be very much better devoted to providing extra accommodation and nurses for the urgently sick, for whom at the present time the chances of obtaining a hospital bed at short notice are very remote '—Dr ROBERT SOUTHBY, *Med J Aust* Feb 17, 1951, p. 245

Before Our Time

THE LANCET'S ANALYTICAL SANITARY COMMISSION OF 1851 AND ITS EFFECTS

LAURENCE DOPSON

ON May 23, 1850, Sir Charles Wood, the Chancellor of the Exchequer, stated in the House of Commons that neither by chemical nor by any other means could it be ascertained with accuracy whether a mixture contained chicory or not The cautious Civil Servant and the answers he drafts for his Minister change little down the years But this negative statement had memorable consequences, for Dr A H Hassall took up the parliamentary challenge and soon afterwards read to the Botanical Society of London a paper on the Adulteration of Coffee, which was widely reported in the daily press He followed it by a second paper on the detection, through the microscope, of impurities in sugar Hassall was already known to Thomas Wakley, the editor of *The Lancet*, for in 1850 he had described in *The Lancet* a microscopical examination of London water Wakley now arranged that Hassall should prepare a series of articles setting out the results of the analysis of samples of foods, beverages, and drugs bought at shops in and around London

Wakley had for many years contemplated running such a series, for in the days when he was an apprentice to an apothecary at Taunton he had seen something of the nefarious practices used in the adulteration of drugs At his suggestion the articles appeared under the title of Reports of the Lancet Analytical Sanitary Commission As editor of *The Lancet* he undertook to bear all the expenses and legal responsibility

DR. HASSALL

Crayon portrait drawn by J N Harland in 1853 (From the *Analyst*, 1929, 54, 567)

AIMS OF THE COMMISSION

The forthcoming publication of the reports was announced in *The Lancet* in 1850, and the first report appeared by the first issue of 1851

In his introductory editorial Wakley showed his skill as a journalist by linking the inquiry with the 1851 exhibition

> "During the presence of the concourse drawn to the metropolis by the Great Exhibition of the Industry of All Nations, the temptation to adulterate articles of food and drink will be immense Against this evil our ANALYTICAL SANITARY COMMISSION will, we flatter ourselves, prove a powerful bar We enter upon the task, then, at an auspicious time, and though unaided, except in the support of the profession, we are determined to execute our self imposed labour for the protection of the public, the advantage of the fair trader, and the ultimate exposure and punishment of the fraudulent one That the duty shall be performed with the most strict and undeviating impartiality, we hope it is unnecessary to offer any pledge"

The editorial also contained this warning

> "Let not any tradesman, mechanic, or manufacturer, imagine for a moment that he can defeat our vigilance We bring the microscope and the test tube—those simple but mighty instruments of modern investigation—to bear with unerring truth upon things hidden and secret enough from the observation of the unaided senses A single glance of the practical microscopist, a single touch of the expert chemist, and the most intricate mystifications stand confessed and marked"[1]

Up to this time, Wakley held, the "mighty instruments of modern investigation" had not been used to defeat the adulteration of food Prout, Liebig, Dundas, and Thomson, he declared, "have devoted the aids and appliances of modern chemistry with the utmost success to the analyses of the ultimate elements of the solids and fluids which nourish the living body, but little or nothing has been done, or even attempted, in the systematic detection of adulterations of these great and universal agencies of health and diseases" In his enthusiasm for his new series Wakley was perhaps being unfair, for some writers had drawn attention to the subject—notably Friedrich Christian Accum who published in 1820,[2] *A Treatise on adulterations of food, And methods of detecting them* This had a dramatic woodcut on the title page showing a skull appearing out of the top of a stewing cauldron on which is written "There is DEATH in the Pot"[3] A second, enlarged edition of the book appeared the same year, in which Accum stated that the first printing of 1000 copies had sold within a month—an indication of the public interest The first section of the book dealt with the adulterations of drugs and medicines, and methods of detecting them, and there was a section on Frauds Practised in the Coal Trade

THE COMMISSION IN ACTION

The motto "Forewarned, forearmed" was printed at the head of every *Lancet* report as it appeared and in each the working principles laid down in the introduction were followed

> First, the reports were to contain the results of actual observation and experiment "we shall borrow but little from the writings of others"
>
> Secondly they were to be illustrated by "faithful engravings"
>
> "A third and highly important feature will be the *publication* of the *names* and *addresses* of the parties from whom the different articles, the analyses of which will be detailed, were purchased"

This publication would not begin for three months, so that retailers and their suppliers would have time to put their house in order, meanwhile only the name of the street or the place would be published

Later Hassall described the care taken over the purchases

> "Two persons in whom confidence could be reposed, were sent out to purchase the articles Immediately on each purchase the name and address of the party was placed on the wrapper containing the article bought, with the date and the initials of the person purchasing I nearly always accompanied the purchasers of the articles, and saw that there could be no mistake or error committed"[4]

The main examinations were microscopical, and it is stated by Filby[5] that Hassall was "aided by several students who were keen microscopists, as well as artists," who produced the illustrations Where chemical analyses were required, Hassall was assisted by Dr Henry Letheby then lecturer in chemistry at the London Hospital Medical College A chemical laboratory was installed at the top of *The Lancet* offices, and investigations were made on the spot The scheme upon which the examinations were made was due to the joint invention of Wakley, Sir William O'Shaughnessy, who had published an article on Poisonous Confectionery in *The Lancet* in 1831, and Hassall. All the reports were written by Hassall, ' subject only to the first approval and revision of Mr Wakley "

[2] Accum F C A Treatise on Adulterations of Food and Culinary Poisons exhibiting sophistications of bread beer wine, spirituous liquors tea coffee cream and other articles employed in domestic economy And methods of detecting them London 1820 Accum was born at Bückeburg Westphalia in 1769 He came to London in 1793, and published a number of books in English on chemical subjects Later he left England and became professor of the Technical Institute Berlin His book on food adulteration was translated into German in 1822 Accum died in Berlin in 1838

[3] *2 Kings*, IV 40

[4] Hassall, A H First report from the Select Committee on the Adulteration of Food 1855

[5] Filby F A A History of Food Adulteration and Analysis London 1934

The introduction to the first report of the Lancet Sanitary Analytical Commission pointed the contrast of the fact that " the urchin who filches a bun, a penny-piece, or the value of one, breaks the law, and is liable to punishment and even imprisonment " Nor was adulteration merely a matter of honesty The physician, having prescribed a carefully planned diet, too often found his well grounded hopes frustrated, because the patient did not in fact obtain the food prescribed. " In one case he orders arrowroot and isinglass—the first is very commonly adulterated with potato, or some other farina, whilst for the second is substituted some ill-prepared form of gelatine." The doctor ordered strong coffee or strong tea, to counteract the effect of some narcotic poison. " The one is adulterated with a large quantity of chicory, and the other consists of exhausted tea leaves redried "

THE FIRST REPORT

Coffee and its Adulterations, the subject of Hassall's original paper, was chosen for the first investigation. Hassall pointed out that adulteration was indeed to be inferred from the fact that, while the consumption of other commodities had increased with the rise in numbers of the population, that of coffee had not, " although, as is well known, the use of a commodity, under the name of coffee, is now much greater than formerly, especially amongst the members of the different temperance and total abstinence societies." Secondly, more "coffee" was sold than passed through the Customs. Thirdly, ' chicory is cultivated in large quantities in various parts of this country, and it is even rumoured that *a minister of the Crown* is himself a large grower of this plant " Little or no chicory was retained as such, and it was in fact found that most of the samples were adulterated with chicory Other substances used were roasted corn, beans, potato, burnt sugar, and a combination of all four Unadulterated coffee was obtained from a shop in Oxford Street and another in Gracechurch Street, which were named, at 1*s* 4*d* per lb and 2*s* per lb respectively The report gave the following " Hints to Coffee Drinkers "—buy the beans, and never purchase coffee in a container, ' for he may be assured that it is even more adulterated than other coffee."

A GOOD PRESS

The reports obtained wide publicity in the lay press From the start the *Times* supported *The Lancet* in its campaign. The editor of the 'Lancet' is entitled to the thanks of the profession and the public for his noble and patriotic scheme,' wrote the *Manchester Guardian* Support came too from the *Commercial Daily List* the *Illustrated London News* and the *Lady's Newspaper* *Punch* wrote

> ' Our contemporary the Lancet has conferred a great boon on the public by establishing a new order of constabulary which may be called the Scientific Detective Police If any of the knaves thus pilloried in the Lancet, abetted by a disreputable attorney and dishonest barrister, endeavour to avenge themselves through the technicalities of the law Punch hopes they will meet with twelve true men in the jury box who will scout both them and their legal accomplices out of court '

Without support from the popular press *The Lancet* could not have reached such a wide circle of readers and influenced public opinion as surely as it did The pages of the *Family Herald*[7] shows the impression made by the commission

> ' In consequence of the recent exposures in the Lancet the grocers are in a state of perturbation, and have divided themselves into an *anti*-chicory and a *pro* chicory party The journal also took up *The Lancet's* argument, and employing the reductio ad absurdum principle asked If we are doomed to suffer adulteration, let us have no monopoly of it. . If it is right to adulterate coffee, why wrong to adulterate the silver spoon with which we sip it '

A correspondent from Bristol wrote that almost immediately after the number of *The Lancet* containing a report on canister coffee reached the city, ' one of the most dashing establishments here suddenly withdrew their canistered coffees from the windows, and substituted bags of roasted, unground. '

The second report on coffee,[8] stated " It appears, that while the prevalence of the adulteration of coffee with *chicory has not undergone any diminution, that* with roasted corn, beans, &c has This satisfactory result we believe to be mainly attributable to the exposures which we have made, and which have done more to check the adulteration of food than has the whole very costly machinery employed for that purpose by the Excise authorities "

Letters to the editor also showed how widespread was the effect of the reports A grocer wrote giving his name and saying that immediately he read the report and realised that adulterated coffee had been bought in his shop, he got in touch with his suppliers, who took the consignment back, explaining that they had not known of the adulteration either, as they were only importers. The grocer was complimented, and others were advised to follow his example A discordant note was sometimes struck, and in the " replies to correspondence " appeared the defiant entry " One who does not Fear the Analytical Commission. We only laugh at such threats . "

The story of the commission's work spread abroad, and later in the same year *The Lancet* quoted a report in the *Ceylon Overland Observer* that a public meeting at Kandy had passed a vote of thanks to " the valuable and unremitting efforts of their friends at home, and especially the talented editor of *The Lancet*, in exposing the numerous and abominable adulterations of coffee and chicory '

FURTHER WORK OF THE COMMISSION

The Analytical Sanitary Commission was concerned not only with sophistication, but with all types of impurities Thus an early report gave truly frightening pictures of the types of organisms drunk by Londoners with their water The first description of the meal mite appeared in the report on bread, this same report also described the development of the yeast fungus The fourth report of the Analytical Sanitary Commission was on pepper This was found to be less adulterated than formerly, because it had been supervised by the Excise authorities. This finding Wakley held to be convincing proof that adulteration could be prevented by inspection, and he made short work of arguments which the Civil Service put up in opposition to the idea. Other reports dealt with sugar and arrowroot

At the end of the three months—in April, 1851—the names of shops where the samples were bought were published Protests there were, of course, though perhaps not so many as might be expected. *The Lancet* published all the replies, but stuck to the validity of its findings. It is perhaps remarkable that there was not a single prosecution against *The Lancet* in this campaign But the following excerpt from the evidence given before the Select Committee on the Adulteration of Food suggests why many traders who would have liked to take proceedings thought better of it

[7] *Family Herald*, 1851, April 15

[8] *Lancet* 1851, i, 465

VISCOUNT GOODRICH You said that in the case of these persons who brought matter to you to analyse, with a view to proceedings against the Lancet, you were obliged to inform them that the articles were adulterated ?

Prof J QUECKETT Yes

Throughout 1851 and subsequently the reports appeared relentlessly In a parliamentary inquiry into the quality of provisions for the troops at the Crimea mention was made of their revelations, and Lord Tennyson wrote

Chalk and alum and plaster are sold to the poor for bread
And the spirit of murder works in the very means of life

Poisonous coloured confectionery was dealt with in articles which appeared in 1854 (At least the names of the sweets sound pleasantly nostalgic—especially "rasher of bacon," "mutton chop on plate," and "oyster fish") But even after *The Lancet* Commission had achieved the passing of an Act of Parliament to control the manufacturer of poisoned sweets, Charles Kingsley was saying in *The Water Babies* "Dr Letheby and Dr Hassall cannot catch them, though they are setting traps for them all day long"

The last of the first series of reports appeared on Dec 23, 1854 [9] In 1855 Hassall undertook the responsibility of republishing all the reports in a single volume [10]

THE PROVINCES JOIN IN

All the reports which had appeared in *The Lancet* up to this time dealt with food bought in London It was, however, in the provinces that the question of the reform which was shown to be needed was first taken up, and in 1854 *The Lancet* carried this significant report "A new local official—viz, a public analyzer, charged with the examination and suppression of adulterations in all articles of consumption, has been appointed by the Town Council of Birmingham" [11]

Mr John Postgate, surgeon and lecturer in anatomy at Sydenham College, Birmingham, led a campaign for national action He had begun work at the age of 11 as a grocer's boy, and so, like Wakley, had early learnt at first hand the facts of adulteration Also he had had a patient who developed purging and vomiting after drinking adulterated coffee In *The Lancet* of 1854 a letter signed jointly by him and Dr A H Browne of Wolverhampton appealed for support from fellow practitioners It further stated that "acting in concert with the movement thus commenced, Mr Scholefield, M P, has already given notice of his intention, early in the next session, to bring the matter before the House of Commons" [12] This led to the establishment of a Select Committee which, under the chairmanship of Mr Scholefield, heard evidence on the question

"Towards the end of the summer of 1855," runs the preface to *Is Killing Murder?*, one of the books which later gave in popular form the evidence before this committee, 'while the good people of England were anxiously awaiting the news of the fall of Sebastopol from the *feu d enfer* of the allied armies, they were themselves bombarded from a room in the House of Commons, where a Committee of members was sitting daily, examining witnesses and investigating evidence as to the truth of the allegations set afloat by the eminent members of *The Lancet* Commission, that the three kingdoms were emeshed in a network of secret poisonings and covert frauds, less tangible, but of deeper dye, than those of the poisoner Palmer, because not only were they more difficult of detection, but, when detected, not amenable to the law of the land Killing was found to be going on, but could not be recognised as murder by law [13]

Wakley, Hassall, Letheby, Dr A Normandy, and Sir John Simon were among those who appeared before this committee, which continued its sittings in 1855 The testimony of Mr Thomas Blackwell, of Crosse & Blackwell, showed how *The Lancet's* work had brought reform He said that his company abandoned the use of copper to colour preserved vegetables "after the articles which appeared in *The Lancet*" At first this prejudiced the sale of his wares, but later favoured it, as the public became educated to the dangers of copper

In 1857 *The Lancet* Commission extended its investigations to the provinces, adulteration was commoner in the provincial cities than in the villages but less common than in London By 1858 the incidence of food adulteration was scarcely 10% of that revealed in the original investigations

It was not until 1860 that the first legislation arising out of *The Lancet's* campaign was passed The Act for Preventing the Adulteration of Articles of Food and Drink provided that parochial chemical analysts could be appointed But the measure was permissive, not mandatory, and, as *The Lancet* pointed out, parish vestries were often composed of the tradesmen who profited by adulteration An amending Act was passed in 1872, strengthening the provisions of the earlier one, and in 1875 came the Sale of Food and Drugs Act, which repealed all the previous anti adulteration legislation Four years later the appointment of analysts was at last imposed as a duty on local authorities

So in the end, helped considerably by *The Lancet's* campaign launched 100 years ago, Britain obtained unadulterated food and drink, showing that even an overcautious parliamentary answer may have an unexpected value

---

Medicine and the Law

What Makes a Nerve Tonic?

Liverpool magistrates on Feb 23 dismissed summonses which alleged that a proprietary preparation was being offered for sale under a label which falsely described it or which was calculated to deceive According to the report of the case in the *Manchester Guardian* (Feb 24), the prosecution stated that a sampling officer had bought a bottle of 'Nervone' "brain and nerve regenerator tablets", the label bore the words "For vim, vigour, and vitality It puts courage into you because it contains one of the most potent nerve nutrients known to modern science" Nervone, said the prosecution, was found to contain 99 7% lactose and 0 3% inorganic matter, of which 0 1% contained five ingredients A Home Office pathologist gave evidence that the words "brain and nerve regenerator" conveyed practically nothing to him, that there was no reason to call lactose a nerve regenerator, and that the amounts of the other ingredients were too small to be of any consequence On the other hand, a medical witness called by the defence stated that he had been practising homœopathic medicine for thirty nine years and that all the ingredients mentioned on the label were recognised homœopathic medicines and were usually prescribed for nervous disorders Another medical witness testified that he had analysed nervone and found the ingredients to be stated on the label with complete accuracy

Counsel for the manufacturers had an easy task in emphasising that, if the prosecution witness did not know what a brain and nerve rejuvenator was, the description could hardly be proved to have been false He could not resist adding the comment that the medical profession would like to drive proprietary medicines out of existence If the proceedings failed, the *Manchester Guardian's* account has at least given readers the choice between the alternative opinions

A Running Commentary by Peripatetic Correspondents

ALMOST every paper written on any branch of medicine or surgery ends with a list of references to previous work in the same field Such is the custom, and few articles would be accepted for publication if they did not respect it But do these references serve any useful purpose, and does the reader ever look them up? The general medical reader whose interests lie elsewhere will never have the time, and the specialist in the same field already knows about them The references are easy enough to obtain A request to the Royal Society of Medicine will bring by return of post a list as long as your arm It seems to me that references are often a form of academic snobbery The longer the list at the end the better the paper appears to be, and many a minor potboiler can be made to look impressive by a skilled librarian with a well-kept card-index Is it not time that Klumpferdinck X (1895) *Munch kleine Nachtmusik*, 79, 5674 was swept away? Mr Klumpferdinck must by now have exceeded his quota of glory

* * *

I was convalescing from influenza X My wife brought me on a tray a glass of water, two capsules of Goddamfiendicol, and the new *Lancet* for March 7, 1952 The *Lancet's* opening paper, by Professor Lilo, should be read and re read by every doctor in the land, and I am quoting the opening paragraphs here, so that doctors going abroad can change their plans

In the course of nutrition experiments on the ruminant skewbald monotesticular rat of Rodriguez (R.S M T R.R) we (Lilo et al 1939, 1946a, 1947b) have noted, on the one hand, an increase of weight that constantly followed the exhibition of brown bread in one colony, and we (Lilo 1948c) have contrasted this with the loss of weight that occurred some time after the withdrawal (forced non availability or F.N.A) of brown bread from other colonies of the same species

'Dr and Mrs Statiks (Statiks and Statiks 1949) have analysed our results and report an obesity rate of 7 015 ± 0 53% They reassure us (Statiks and Statiks, personal communication over a cocktail) that the exact significance of our work can never be established This encouraged us to neglect further, for the moment, the starved (F.N A) rat (Lilo 1949c) in order to give our full attention to the brown bread fed skewbald ruminants (B.B.F S R) As a result of the rush at feeding times certain injuries have become frequent, and the subjects of these strains (Sans Humo s 'loads) walk now with a characteristic sideways scurry The resemblance of their gait to that of people (*Homo sapiens occidentalis*) with alleged herniation of a slipped lumbar disc struck us from the first (Lilo 1950 and 1951b) and excellent results have followed operation in certain selected cases (Lilo 1952 in press) It is much regretted that the opportunity thus offered of comparing the results of manipulation (Kenon 1950) with those of operation (Burnhem Yung 1951) could not be taken, accurate handling having been persistently opposed by the strained B B F S.R 's "

The references to Professor Lilo's previous articles are not given in detail because they have been worn threadbare by keen reading and are no longer legible I was glad to see, however, that, in response to the widespread demand, Professor Lilo has arranged for his experimental work, with all the relevant literature, to be published in quarterly instalments, panoramic diagrams in brilliant colours being included as a free-gift supplement with each issue Postcards, with cheques attached, will receive his personal attention

Note —The Institute of Interpreters of Medical Literature (INSINTERMEDDLE) informs me that its Fellows are always available to help would-be readers and that a 24-hour service is being maintained for the duration of the Festival of Britain

* * *

Four years ago, when I had the temerity to write in these columns some (illustrated) hints to brides on answering a doctor s telephone, I thought I knew all about the G.P 's evil genie But I didn't, not by a long chalk In all humility I now cry for aid

A woman at the far end of the town has a telephone number almost identical with ours Just a single numeral misdialled and the public get her instead of us One evening when she was playing bridge she was disturbed by a call from someone wanting my husband She lost no time before complaining to me "You must do something about it," she demanded, "when one has friends in for bridge one cannot be disturbed" I obediently notified the Post Office They turned up trumps, as usual, and did various tests Their sympathy was with us and they rang her several times from our house. When she lifted her receiver she heard "Post Office testing," and then the line went dead That kept her quiet for about six weeks, but now she's at it again "You *MUST* tell your patients your number clearly," she told me, "can't you put it up somewhere?" With mounting hysteria I told her it was on my husband's plate, on his prescription pads, on our note-paper, and in Mr Marquand's lists at the post offices "Then people must be very stupid," she said As cuttingly as I could I replied, "They are" But there must be a snappier retort than that, can any fellow sufferer recommend a really flattening one?

What with the smallpox and then the flu, my husband has taken to picking up the phone when it rings, listening to the gist of the message, and if it isn't urgent saying "I'm sorry he's engaged with a patient, ring later" Then, patting himself on the back, he sets off to do another score or so of calls, leaving me to cope with the "rings back." This morning the long line of flu, constipation, wind-round-the heart, and depression was at last broken by a cheery call from our normal and healthy curate about his jumble-sale I could have kissed him on both cheeks What a relief to speak to someone who hasn't been ill, isn't ill, and doesn't intend to be ill if he can help it!

* * *

Be good, G.P, and let who will be clever
Stitch up those cuts, don't send them all along
To hospital, where patients wait for ever
And later make
A fearful song

* * *

With most of us in a state of postinfluenzal depression, tea in the laboratory was a dreary affair The talk ranged gloomily from atomic warfare to the class-Z call up, from the cost of living to the 8d meat ration, and ended, aptly enough, with Death and the Manner of Dying We recalled memories of student days when every pain in the knee betokened osteogenic sarcoma, when the slightest cough foreshadowed a carcinoma of the lung or sarcomatous metastases, and when tummy-ache was an almost certain sign of inoperable gastric cancer In those days, of course, we all knew in our secret hearts that we had T B, and felt sure that in the end, if our tumours did not kill us first, we would be found in the digs coughing our last over Price's *Textbook of Medicine* With brave sad smiles playing about our pallid lips we pressed on regardless Eventually, to our own surprise and our teachers' amazement, we qualified The crutches were flung away, the sarcomas and carcinomas regressed, and the lungs became as new From that day on we were far too busy to worry about our health But today brought back all the old fears and we were a glum crew as we discussed how and when the last curtain might fall We envied the one colleague who knows how and roughly when he is going to die, if (so to speak) he is spared until then For generations all the men in his family have died suddenly in their fifties As he himself said ruefully, "In our family unless you make something of your life before you're fifty, chum, you've had it" Apparently their coronary vessels just don't or won't anastomose, so his relations go out like lights at regular intervals He is convinced that if any of them did reach the sixties his body would fall victim to all sorts of diseases, and he would die, "Riddled, my boy, absolutely riddled" With these gay words ringing in our ears we crept back to the lab and thence home to read Schopenhauer's *Studies on Pessimism*

Aphorism of the Week

The nearer the bone the safer the surgeon

Letters to the Editor

SPECIALISATION

SIR,—Though there were many other and important suggestions in Dr. Todd's article of Feb. 24, I would like to pursue further one particular argument about the general practitioners' need of facilities for diagnosis which too often at present they lack. Dr. Todd argues the need for "health centres where general practitioners could have the more important investigations done. For ... no doctor can be efficient without the aid of certain X-ray films, blood counts, urinary examinations, and a few other tests." And he rightly attributes the overcrowding of medical outpatient departments of hospitals, in part, "to the attendance of patients whose general practitioners desire, not a second opinion, but an investigation which they cannot get done themselves."

Lest general practitioners should be once more and still further discouraged by having dangled before them, as the chimerical solution of all their ills, "health centres" which they (and all of us) know cannot now be built—at any rate to the scale originally envisaged—it may be opportune to discuss rather simpler, certainly less expensive, and perhaps more acceptable alternatives.

The Nuffield Provincial Hospitals Trust is hoping to be able presently to put to practical test a "diagnostic centre" for general practitioners in the town of Corby. The idea is not that the practitioners of Corby and the surrounding villages should transfer the whole of their practices to a central building, but rather that they should refer to the "diagnostic centre" such of their patients (estimated by the general practitioners themselves at about a quarter) as require detailed diagnosis and special diagnostic tests—whether by the general practitioner unaided or in consultation with specialists. The centre would be equipped with X-ray facilities and a pathological laboratory, to be provided by the Regional Hospital Board, and specialists would attend on specified days to see patients and consult with the general practitioners. (In addition, the Regional Hospital Board intends also to provide, on the site, a maternity block for uncomplicated midwifery; and, in the more distant future, perhaps general practitioner beds. Ultimately it is hoped that the local authority clinics would be erected on part of the same site.)

The need for such a centre arises in Corby from considerations at least as much of the patients' as of the practitioners' convenience: the nearest hospital, at Kettering, is 7 miles away. What, in effect, it is hoped to attempt is a combination of (*a*) general practitioner consulting rooms, with diagnostic aids (and simple treatment rooms), and (*b*) an outstation, in Corby, of the Kettering outpatient departments—so that general practitioner, patient, and specialist may meet where the facilities for full diagnosis are centrally and conveniently provided. That the specialist can consult personally with the general practitioner, on the general practitioner's own ground, rather than correspond impersonally from a hospital outpatient department, may be a significant step towards the development of something nearer to domiciliary consultation.

Whether this "diagnostic centre" at Corby will be realised depends on many factors outside the Trust's control. But at least we have thought it right to attempt to throw this bridge across the gulf which at present divides the services provided under Parts II and IV of the National Health Service Act. The enthusiastic reception of the proposal by the local general practitioners has been of the greatest encouragement to the Trust.

L. FARRER BROWN
Secretary, Nuffield Provincial Hospitals Trust.

12, Mecklenburgh Square,
London, W.C.1.

SIR,—Dr. Todd suggests (Feb. 24) that clinical registrars should be selected from the ranks of general practitioners, and that the minimum period spent in general practice should be three years.

It has become the fashion to set up committees to inquire into the ways of improving the standards and working conditions of general practice. Dr. Todd now draws attention to the shortcomings of the specialists.

There are four groups of cases which are referred to the hospital specialist:

1. *Cases for outpatient treatment.*—For example, a case of obvious arthritis in which physiotherapy is the only suitable treatment—but the patient must first be seen at the medical outpatients department.
2. *Cases for laboratory investigation.*—For example, a case of anæmia where a blood picture is required in order to decide on appropriate treatment; or a case of glycosuria where a blood-sugar estimation is required in order finally to establish a diagnosis.
3. *Cases for inpatient treatment.*—For example, where domiciliary treatment is difficult, impossible, or undesirable.
4. *Cases for diagnosis.*—Where the general practitioner is completely unable to arrive at a diagnosis, and a second opinion is necessary.

As a general practitioner, I have discussed with colleagues both in this area and in other parts of the country the often grave deficiencies of the younger school of specialists and consultants. Perhaps I am cynical or unfortunate, but out of every ten Group 4 cases referred to consultants of the younger school, the diagnosis evades the consultant's clinical examination in nine instances, and after full laboratory investigation he is still in the dark in six out of the nine. Where a confident diagnosis is made, he is ultimately proved wrong, in whole or in part, in 50% of cases.

Specialists will, no doubt, hotly contest my figures, but I would refer them to the paragraph headed "Diagnosis in the Broad Sense," in Dr. Todd's article.

In his second paragraph, Dr. Todd appears to suggest that the following four factors go to make a specialist: brains, luck, money, or influence. Since we all have brains, of sorts, it might be more accurate to substitute for the word "brains," "flair for academic examinations." There are, of course, other influences which rightly contribute to a man's success—e.g., pertinacity and thoroughness. But there is one great factor which cannot be acquired quickly, and that is *experience*. It is on this count that the young consultant or specialist falls lamentably short, and it is for this reason that he so often fails in what I have termed the Group 4 cases. On extremely rare occasions, however, clinical brilliance may make good this deficiency.

What can the profession do about it? Obviously, it is impossible to present the younger specialist with a period of "twenty years' experience" as though it were a pound of cheese. Similarly, we cannot bestow brilliance of intellect upon a body of men whose mental calibre is no different from that of their general-practitioner colleagues.

I would suggest that no one should attain the rank of consultant before the age of 45 at the earliest. The intervening years would be spent as "general practitioner–hospital registrar." At least half of the working day and night would be in general practice, and the other half in hospital practice. As to remuneration, this would be based solely on his general-practitioner work. His list would be half the current maximum, but the scale of remuneration would be double the prevailing rate.

This "general practitioner–registrar" would then be competent to deal with all cases in Groups 1, 2, and 3, with a consequent saving in registrars' and specialists' salaries. The true consultant would once more regain that prestige and respect from his colleagues, which, alas, is fast dying out.

J. S. WOOD.

Bootle, Liverpool.

SELF-IMPROVEMENT DISCOURAGED

SIR,—One of your recent leaders stated that Disraeli's Two Nations had virtually disappeared. Whether or no this is so, there is no doubt that Two Nations are rapidly developing inside the profession.

There is a widespread feeling that the general practitioner, often referred to as the salt of the earth but apparently regarded as the soul of incompetence, should improve himself or be improved. Now if the elderly general practitioner tries to improve himself by reading in his scanty leisure for a diploma of some kind, say in obstetrics, he will find himself thwarted at every turn unless he has held, or is able and willing to take up, a whole-time resident appointment at an approved hospital for six months. Failing this he is simply not allowed to sit for such examinations. No credit whatsoever is given for knowledge and experience acquired in 20 years or more of private practice.

Surely the acid test of admission to an examination should be *whether or no* the candidate possesses the requisite knowledge and experience, not *how* he has acquired them. The present situation is not only manifestly unfair to the general practitioner who wants to be a better general practitioner, but, what is more important, unfair to his patients and trainee assistants (if any). What is to be feared from admitting to these examinations general practitioners of experience? If they are not good enough to pass it is easy enough to plough them. If, having worked for them in their spare time, they are good enough to pass, who is worse off? Is there an apprehension lest some of them might wish to leave general practice and attempt to become consultants? Not a very real danger, I fancy, from those of riper years.

Crediton. L. N. JACKSON.

NURSING INFECTIOUS DISEASES

SIR,—Twenty-five years' fairly close study, as a layman, of nursing recruitment, and of the channels of tuition and experience by which the general body of qualified nurses is fed, convince me that the best nurse is made on a basis of fever training. So much of the material of nursing (in and out of hospital) comes from the very large group of diseases based on infection, and so much of infection accompanies many others, that it is difficult to see how the General Nursing Council can do other, if it is at all forward looking now, than use the infections as the core of nurse training, rather than as a casual extra.

Granted that there is no longer a case for the continuance of hospitals specialising wholly in "fevers," there is a solid case for the one-time sizable London fever hospitals (500–600 beds) keeping infectious disease units of, say, 200 beds and building up special units (tuberculosis, non-surgical children, &c.) on this most valuable basis, and using their nurse-training resources to provide the tuition in the infections which they can so brilliantly give.

The smaller outlying ex-fever hospitals can, if they are not too ancient—and they modernise easily—play their part also. (They are, incidentally, the hospitals which, properly handled, can take the tuberculosis challenge in their stride.) Any group fortunate enough to have an ex-fever hospital not only has the answer to the development of group nursing, but, in applying it, can straight away smash the evils outlined by Dr. Stanley Banks.

There is room for the thought that, in London, the severe lesson of 1938 and the Sonne bacillus has been too easily forgotten if ever really learned: that there is altogether too much regard for the possibilities of using fever hospitals as decanters for unwanted clinical material elsewhere: too little for their potential value in their own field and in the production of the complete nurse.

The reasoning, logical in the conditions of the mid-19th century, which separated the handling of fevers from day-to-day general-hospital work has now become an unpardonable habit of thought.

St. Mary Abbots Hospital,
London, W.8. W. J. CRABB.

METHONIUM COMPOUNDS IN HYPERTENSION

SIR,—Recent reports have described encouraging results with the methonium compounds in the treatment of hypertension. As these drugs are now freely available and are, to our knowledge, in use in general practice, we believe that those who experience unfavourable results should make the facts known. We therefore wish to record the following fatal case.

A married woman, aged 47, was admitted to hospital on Jan. 3, 1951. She had a long history of migraine and of hypertension, with severe generalised headache for two years. One month before admission she had a violent headache followed by transient dysarthria and dyslexia. The family history was strongly positive for both migraine and hypertension.

The patient was obese. There was a small non-toxic thyroid adenoma. The heart was moderately enlarged, with a thrusting impulse; there were no murmurs; triple rhythm was absent; and no evidence of cardiac failure was found. The retinæ showed arterial hypertensive changes only. Neurological examination was negative except for trivial hesitancy in reading and writing. The blood-count was normal; the urine showed no abnormal constituents or deposit; the blood-urea was 31 mg. per 100 ml.; and the electrocardiogram showed the pattern of left ventricular hypertrophy.

On admission the blood-pressure (B.P.) was 236/160 mm. Hg; this settled overnight to 180/120, and it fell to 136/90 after three doses of 'Sodium amytal' gr. 3 at hourly intervals.

Treatment with hexamethonium bromide was initiated in view of the high diastolic pressure, persistent and incapacitating headaches, and the history of a resolved cerebrovascular incident. An initial intramuscular test dose of 50 mg. reduced the B.P. only to 160/110 mm. Hg. Single daily oral doses were then begun, with hourly B.P. recordings, the dosage being increased until an adequate hypotensive effect was obtained. This practice has been followed by us in order to obtain a record of the degree, duration, and variability of response to single doses before increasing the frequency of administration. The B.P. did not fall below 140/90 mm. Hg until a dose of 2·5 g. was reached: this produced a reading of 120/90 mm. Hg six hours after administration. Vision was blurred and there was some nausea. The next morning the patient vomited and the B.P. was only 115/75 mm. Hg; but it had risen to 165/115 mm. Hg by the afternoon. Investigations into the possibility of a coronary thrombosis gave negative results. The patient developed diarrhœa, and it was thought that the condition was possibly a coincidental infection—a conclusion which in retrospect we doubt.

Hexamethonium bromide was withheld for six days and resumed at the same dosage for nine days with relief of symptoms, side-effects being slight and variable. The lowest B.P. readings were noted between one and eight hours after administration of the drug and ranged from 110/80 to 170/124 mm. Hg. The responses showed no progressive pattern and there was no significant variation in the preliminary B.P. readings before each day's dose. On the tenth day the dosage was decreased to 2 g. on account of side-effects. The initial B.P. was 190/120 mm. Hg, and three hours later the B.P. was 120/90 mm. Hg: at that stage the patient fainted on standing up. Thereafter the B.P. fell still further and by the next morning it was 80/50 mm. Hg, the patient meanwhile having started to vomit large amounts of clear green fluid. Intramuscular methedrine produced only a small and temporary rise in B.P.; and though dehydration was prevented by saline infusion the B.P. remained in the region of 80/60 mm. Hg. Intravenous adrenaline was then used; and as there was an immediate response in the B.P. an intravenous saline drip containing adrenaline was set up and the dosage, using "booster" doses when necessary, was adjusted in an attempt to maintain the systolic pressure over 140 mm Hg on the basis of recordings every fifteen minutes or less A steady increase in dosage was necessary and the patient died after twenty one hours, having had a total of approximately 70 mg of adrenaline For almost the whole of that period the required B.P level was maintained, but the pressure always dropped precipitately during the brief periods when the drip was discontinued

Autopsy showed no cardiac infarction and no unusual or severe renal lesions A small cerebral cyst, filled with altered blood, was present in the parietal region on each side

Through the kindness of the research department of Messrs May and Baker Ltd , the hexamethonium bromide content of the last three urine specimens collected was examined In the last twenty four hours of life only two catheter specimens, totalling 13 ml , were obtained, together containing 7 5 mg of the drug , previous specimen twenty seven hours before death contained 55 2 mg There was no methonium in the vomitus, which had a chloride content of 352 mg per 100 ml

We wish to stress that this patient, under careful supervision in hospital, entered an irreversible, progressive, and fatal hypotensive state after an oral dose of hexamethonium bromide smaller than those which she had previously taken without alarming or consistent reduction in the B P Further, no progressive fall in the initial morning B P had occurred to suggest a cumulative effect Indeed, the high chloride content of the copious vomitus (260 oz) makes it questionable whether death was due simply to sympathetic blockade Earlier use of adrenaline might have averted the fatal outcome, but continuous therapy for twenty one hours was unavailing

We have reason to believe that this is not the only tragedy which has occurred with the methonium compounds, and we doubt whether it is justifiable for these substances to be used at all outside a hospital Disasters are probably inevitable in the early stages of experience with any new and potent drug, but the course of hypertension is so unpredictable, particularly in women, and the response to hexamanthonium bromide has been so unreliable in our experience, that we do not propose to use these drugs again except for patients in whom a relatively early death appears inevitable with any other form of medical treatment

SPINAL ANÆSTHESIA

SIR,—The arguments of your annotation last week justify disuse of spinal anæsthesia for merely securing abdominal relaxation Unfortunately the considerable prejudice against it, especially in obstetrics, has prevented its use in conditions where there is increasing reason to think it valuable Evidence of its efficacy in eclampsia and anuria is being sporadically reported, and Hingson has provided a long list of successes In interpreting his method of Pavex caudal analgesia it becomes clear that he aims at a " denervation " of the kidney and at avoiding a fall of blood pressure meanwhile In eclampsia low spinal block is equally effective The meagre fall of blood pressure herein ensuing cannot be held responsible for the improvement It is reasonable to assume that these two almost similar procedures have a common target In the Hingson technique it is the kidney directly In the other the same organ is indirectly involved by interruption of a uterorenal reflex No other explanation comes to mind Shorr's work on V E M and V D M would explain postoperative shock through the mediation of the kidney, and should be an incentive to the anæsthetist to devise methods of insulating that organ from stimulation during major surgical procedures Here again caudal anæsthesia is the goal The decline in the practice of spinal anæsthesia will blur a new horizon needlessly

J SOPHIAN

PROPHYLAXIS AGAINST TETANUS IN BURNS

SIR,—In his review of burns and their management (Feb 24, p 460), Mr Clarkson advises that " Antitetanus serum should certainly be given in all cases," and he suggests that active immunisation of the whole population should be seriously considered He bases this advice on the fact that Dupuytren mentioned the risk of tetanus in burns over 100 years ago, and on Dr Altemeier's report to the recent Washington Conference of " an incidence of contamination by tetanus organisms of 3% in routine smears from primary burns " I have looked up Dr Altemeier's published work on the bacteriology of traumatic wounds (two papers, one of which mentions 13 burns) but I have found nothing to support the idea that true tetanus bacilli frequently contaminate these latter injuries I did not hear Dr Altemeier's statement in Washington, but I think it unlikely that he would rely on " routine smears " for the positive identification of tetanus bacilli

However, quite apart from this evidence, I wonder how often Mr Clarkson has encountered, or heard of, tetanus as a complication of burns in this country ? I have no doubt it may occur occasionally but in the course of 8 years' contact with burned people (about 6000 cases) I have not experienced it I realise that there are likely to be other injuries in the event of an atomic " incident " over this country, and active immunisation of the population might well be worthy of consideration in connection with them , but I question whether we should inflict yet another injection, and the risk of serum sickness, on those who have only burns

Farnham Royal

LEONARD COLEBROOK

EXPERIMENTAL GLOMERULONEPHRITIS

SIR,—Heymann and Lund,[1] Solomon et al ,[2] and Pressman et al ,[3] using improved methods, have confirmed the glomerular origin of the antigen that gives rise to nephrotoxic serum In consequence the observation by us of the nephrotoxic effect of anti rabbit stomach serum was unexpected

We immunised ducks by intraperitoneal administration of antigen prepared from rabbit stomach, and injected intravenously into the rabbit the serum thus obtained A pathological process ensued which clinically and histologically resembled closely acute and subacute glomerulonephritis in man

The manifestations of nephritis, which appeared after a latent period averaging six days, were albuminuria, microscopic hæmaturia, cylindruria, hypertension, water retention, and occasionally anuria These manifestations developed in the course of a few days and this sudden onset reminds us of anaphylactic reactions The animals either recovered or died of uræmia It seems remarkable that experimentally, as in man, uræmia is preceded by hyposthenuric polyuria

Necropsy usually revealed a large white kidney , among 12 animals we found only 1 granular kidney In 3 cases we found multiple bleeding gastric erosions, but peptic ulceration had not developed

Histological examination showed that in some cases virtually all the glomeruli were affected , and the pathological changes were diffuse In the glomeruli could be discerned the specific capillary reaction accompanied by local anæmia that characterises the disease in man The loops, despite occasional extreme dilatation, did not contain red blood cells These peculiar empty loops recalled Froehlich's *Plasmalücke*,[4] which is a local anaphylactic phenomenon In the exudative phase the dilated cavity of the glomerular capsules was filled with albumin , in the proliferative phase the size of glomeruli was almost doubled, owing to endothelial proliferation. In certain places the loops and capsule adhered; elsewhere half-moon formation appeared.

As a control two rabbits were given two intravenous injections of 20 ml. of normal duck serum. The animals have been observed for eight weeks, during which no abnormality has become evident.

From these findings we conclude that the glomerulonephritis described is a specific process, the pathogenesis of which is to be found in an antigen-antibody reaction, and that the rabbit stomach contains what may be called "heterotopic antigens," identical with those in the glomeruli. In the duck these heterotopic antigens evoke specific nephrotoxic antibodies.

Our experience does not refute Masugi's[5] theory of the specific origin of nephrotoxic nephritis, and it provides additional evidence of the allergic origin of the disease in man. Our findings do, however, show that not only kidney antigens but also heterotopic antigens can give rise, by an immunological process, to glomerulonephritis.

CORONARY DISEASE AND MODERN STRESS

SIR,—Dr Stewart (Dec. 23) gives the following comparison of occupational groups with regard to death from coronary disease:

Agricultural workers	32
Coalminers below ground	40
Banking and insurance officials	183
Anglican clergy	218
Physicians and surgeons	368

He says that these figures are remarkable and significant. No doubt they are; but what is their significance? He suggests that the differences are proportional to the degree of mental stress in the classes mentioned. Are they not just as likely to be inversely proportional to the amount of physical work done by the classes concerned? At the present time agricultural workers do more work than any of the other classes mentioned. Physicians and surgeons do the least. They rarely even walk. Some clergy and some banking and insurance officials do. If one postulates that physical work is a preventive of coronary artery disease, then the figures quoted by Dr Stewart fit in perfectly. This hypothesis would also agree well with Dr Stewart's statement that members of primitive races are immune but lose their immunity when subjected to civilised life. He says that two main influences are brought to them by civilisation, unfamiliar stress and increased richness of diet. But as Dr Percy Stocks points out (Feb. 10) there is also a third factor—a decrease in physical effort.

It is also in favour of this hypothesis that the differences in physical work are a known factor, whereas the differences in mental stress are merely a suggestion put forward by Dr Stewart. I wonder whether the manual workers have as little mental stress as he imagines. When we start weighing other people's mental stress we are apt to fall into error. Does the manual worker as he feverishly turns over the evening paper to see if the second leg of his double has come up in the 4.30 experience more or less stress than the doctor who lies awake at night wondering if he can afford to send his son to his old school? Who knows?

I have put forward one hypothesis which I think fits the facts given us by Dr Stewart as well or better than his modern stress theory. There are of course other hypotheses which would fit his facts just as well, but it is not necessary to elaborate them, for my purpose has been to show that the identification of sufferers from coronary disease as the selected victims of modern stress may not be as reasonable as Dr Stewart suggests.

In an effort to prevent this letter from being entirely destructive, I put forward rather hesitantly some personal speculations.

I think that long periods of hard physical labour continued over a long time are bad for the cardiovascular system, and if carried to the extreme degree will cause serious cardiovascular degeneration. In these cases the coronary arteries tend to be calcified. On the other hand, absence of physical activity tends, I think, to produce degenerative changes in the coronary arteries, and this degeneration shows itself in the formation of atheromatous patches.

It seems to me that hard physical work for relatively short periods may have a protective effect on the coronary arteries. We know that hard physical exercise greatly increases the flow of blood through the coronary arteries, and it may be that this increased flow benefits the condition of the arteries. We know also that hard physical exercise produces considerable movement of the diaphragm, and this seems bound to affect the coronary circulation.

I know well the dangers of putting forward unsubstantiated hypotheses to solve medical problems, and in this case I have taken the risk for two reasons—(1) because we have had little help from the scientific investigators, and (2) in the hope that further investigations may be made. There are two simple investigations which might throw some light on this problem: a comparison of the incidence of coronary artery disease in scholastic teachers and physical instructors, and a careful investigation of the condition of the coronary arteries in racehorses, particularly a comparison between those which continued in training till they were aged and those which were retired to stud as three-year-olds.

BACTERIAL VARIANTS PRODUCED WITH CHLORAMPHENICOL

SIR,—In the interesting articles by Dr Voureka in your issue of Jan. 6 there are three points on which I should like to comment.

(*a*) The only mention Dr Voureka makes of the type of urine specimen she examined is in connection with case 2, in which "samples of mid-stream urine were plated." She does not say how the other specimens of urine were obtained, or whether her patients were men or women; and one wonders whether this intricate and detailed work may not have been carried out on organisms not representative of those causing the initial infections in the patients' urine, for non-catheter specimens are notoriously misleading.

(*b*) Dr Voureka stated that, when *Bact. coli* D433 was exposed to chloramphenicol alone, no stable atypical colonies were obtained throughout the experiment. "It was then thought that special conditions in the body might have influenced the production of these forms. . . ." She draws an analogy between the effect in vitro on *Bact. coli* D433 exposed to both chloramphenicol and a specific antiserum and the effect obtained when she carried out her painstaking cultural investigation on urines of patients with *Pseudomonas pyocyanea* and coliform infection. This might be an unfortunate analogy, for another worker in the same laboratory, W. H. Hughes,[1] has emphasised that cases with urinary infections develop no agglutinins; he made use of this observation in recommending that vaccine therapy should be followed by chemotherapeutic agents, when a chemotherapeutic agent by itself would not produce a cure. Therefore I assume that Dr Voureka's cases probably had no agglutinins in their serum to produce an effect analogous to her in vitro experiments on *Bact. coli* D433. Except for some unconfirmed work by Giles, no one investigating cases of gastro enteritis associated with *Bact coli* D433 has demonstrated the production of antibodies by the patient harbouring these organisms , so it would seem that on two critical points the analogy Dr Voureka draws is an unfortunate one

[1] Hughes, W. H. *Proc. R. Soc. Med.* 1943, 36, 477. Paper (unpublished) read at Summer meeting 1948 of the Pathological Society of Great Britain and Ireland.

(c) For those who work with the specific strains of *Bact coli* it is a problem to know what names should be given to the strains so far identified We have Bray's original name of "var *neapolitanum*,"[2] Giles and Sangster's "alpha,"[3] and Joan Taylor's "D433,"[4] all referring to the same specific strain of *Bact coli* I and my colleagues[5] may have also confused the issue, when we were only working with this strain, by referring to it as "B G T," the initials of these first three workers Smith[6] isolated a second specific type of *Bact coli* and this has been labelled "beta"

Now that there are other specific types of *Bact coli* which are found intimately associated with infantile gastro enteritis in different epidemics, it is more than unfortunate that Dr Voureka has allowed *Bact coli* D433 to have these three children—the variants alpha, beta, and gamma—particularly as the alpha antigen of Stamp and Stone[7] (for which priority must be claimed) is a surface antigen which may be found on some strains of *Bact coli* A study of the literature reveals the confusion that has arisen in the use of such names as those employed by Dr Voureka

KWASHIORKOR

SIR,—Dr MacPherson (Jan 6) believes that *Kwashi orkor* is the native name for a form of "ju-ju" or devil possession, and not the name of a disease, as previously stated by Dr Cicely Williams

Infantile pellagra, or nutritional œdema, is recognised by all the peoples of the Gold Coast, under various names *Kwashiorkor* is used by the Ga (Accra) tribe, while other names are *Akwosi* (Ashanti), *Abusamba* (Fanti), *Kpagyavi* (Ewe), *Tari* (Busanga), and *Jeredi* (Low Hausa) Of these, only *Kwashi* or *Kwasi-orkor* appears to be a descriptive name, the others being specific titles of no known derivation *Kwashi* or *Kwasi* is the name given, not only by the Ga and Akwapim peoples but by most of the Akan tribes, to a male child born on Sunday It is also used, much as "Tommy" or "Jock," to attract the attention of a boy whose correct name is not known *Orkor* means "red" The disease is characterised by pellagrinous patches on the skin, which appear reddish in colour against the normal black brown of the African skin , but, more evidently, the hair is thin, brittle, and rusty in colour The restoration of the hair to its normal curly glossy black is the final criterion of cure

I have asked lay people of the various tribes, who are knowledgeable in native lore, for descriptions of the disease With only minor variations I have been told that "when a woman, who is suckling her infant, becomes pregnant again, she must put the child away from the breast in order that her strength may go to the fœtus" (One or two tribes say that her milk becomes poisonous to the child) "When the parents are poor the infant cannot get any proper substitute for its mother's milk, and so gets the sickness" (This is, of course, a free translation from the vernacular) Normally, breast-feeding continues, with or without supplementary feeding, until pregnancy again supervenes Intercourse is forbidden for a period varying from twelve to twenty four months after parturition , hence deficiency disease is most common among children in the second and third years It is interesting to find that, among the Northern peoples, the care of the child, newly weaned, devolves on the father, who presumably shares with it the more digestible portions of his own food, which is rich in proteins

Where native opinion, everywhere, expresses the correct ætiology of the disease, it is unlikely that the Ga name derives, as Dr MacPherson considers, from possession by evil spirits Indeed, since reading his letter, I have questioned, specifically, Africans who are usually pleased to discuss with me "ju ju" and allied subjects I have met with denial of knowledge of any such belief, and kindly, though pitying smiles, which are my portion whenever I make a gaffe about native customs However, I must agree with Dr MacPherson in one thing The "casting out of devils" is an essential part of the treatment The "exorcism" is performed with santonin and calomel

Bogosu,
Gold Coast

J M DONNELLY

MUNCHAUSEN'S SYNDROME

SIR,—Dr Asher's first case uses his "Buckingham shire" name when he visits us I wonder if any enthusiastic surgeons have noticed the ileotransverse colostomy which we performed in 1944 for fæcal fistula One month later he was in for a few hours after which we heard that in Liverpool His Majesty had some interest in his welfare By 1948 he was chief officer, Australian Merchant Navy, and had been blown up at sea His story and his abdomen were embroidered with steel wire (not confirmed by X rays) While he was obviously perfectly well, his abdomen was enormously distended Letters to addresses in Dalkeith and Bristol elicit replies from a wife who has disowned him for years and a lady who is "tired of getting wires about him" The letter suggests two other names he may be using Having been "shot down in Germany" he looked us up in June, 1949, was recognised, and discharged himself at 6 A M next day

Dr Stretton's case (Feb 24) is also well known at this hospital

Mile End Hospital,
London, E 1

S WILLSON HOLMES
Surgeon

TRAINING OF INVALID CHILDREN

SIR,—In your issue of Feb 24 Dr Field asks "What is the best way of looking after lame ducklings ?" Her letter is not easy to follow The Invalid Children's Aid Association's appeal for funds for a new home, despite an overdraft on current account, clearly disturbs her The Association's executive and finance committees, while sharing her concern about the overdraft (all contributions thankfully received !), are not one whit disturbed at the prospect of increasing their capital in the form of a new Home Their task here is to help any family burdened with the care of a chronically sick or handicapped child by giving the child a holiday and the parents a break

Dr Field wonders how far time and money should be spent on children who may never become useful citizens Perhaps the lessons learned by the I C A A in England may help her in Malaya The Association, some sixty years ago, took over from the squire, the parson, and the kindly neighbour some of the growing work of the care of invalid children It mobilised the charitable impulses of those with time and energy as well as money to spare It found what work needed doing and devised methods of doing it The aftercare and rehabilitation of hospital patients, including convalescent treatment and the follow up of cases after their return home, came first Then came the establishment of Schools of Recovery for long term cases, such as the well known Heart Home at West Wickham, and, at Dr Field's own suggestion, the Meath Home for children with bronchiectasis The Association's work in these fields has become a common place in pædiatrics This is not the place for a full account of all its activities, but the Association still regards it as a duty to find, and to seek to fill by voluntary effort, gaps in the social service to invalid and crippled children This does not prevent coöperation over such statutory work as is delegated to the Association by regional hospital boards and local authorities

[5] Rogers K B Koegler S J Gerrard J *Ibid*, p 1501
[6] Smith, J *J Hyg Camb* 1949 47 221
[7] Stamp, Lord Stone D M *Ibid* 1944 43 266

Now with the growth of the Welfare State two things happen First, voluntary societies become more concerned with the gaps and with the difficult and the expensive problems Secondly, the cost of a State service, trying to be comprehensive, soon becomes prohibitive Already there are signs of rationing and a loss of amenities hitherto enjoyed—unless voluntary endeavour comes to the rescue The Association firmly believes that a great part of social work among children can only be carried on by voluntary societies

Dr Field will not expect to apply in one plan all the methods that have grown slowly and solidly in England in the last hundred years She should find and tackle whatever are the most urgent social problems of Malaya's invalid and crippled children She must build on whatever foundation has been laid by missionary and other philanthropic societies in her community In time and with experience of doing what lies closest at hand she will become less interested in "priorities" and "best methods" and more content just to do as much as can be done for as many children as possible, and Malaya's progress in civilisation will, in Professor Moncrieff's terms which she quotes in her letter, be judged by how much the community cares for its lame ducklings

DEFINITION AND NOTIFICATION OF TUBERCULOSIS

SIR,—The letters of Dr Stewart (Feb 24) and Dr Barran (Feb 10) are timely and important, because the Ministry of Health is considering new regulations for the notification of tuberculosis Notification may be a dry "subject," but all will agree that progress in public health has depended and will depend on knowledge obtained from compulsory notification

The Minister of Health's Standing Advisory Committee on Tuberculosis has wrestled recently with a definition of tuberculosis and sent a draft for consideration to the Joint Tuberculosis Council. The definition of tuberculosis should not be considered in isolation but in connection with other possible or desirable alterations to the present regulations for notification, including intimation (provisional notification) Intimation has I understand, been a useful and successful part of notification in Northern Ireland under the Public Health (Tuberculosis) Northern Ireland Act

The Ministry have not incorporated, so far, in their proposed new regulations, any recommendation that notification should be in two stages (*a*) intimation (provisional notification) and (*b*) registration (full notification) A general practitioner under the National Health Service Act, by his terms of service, must refer any patient whose condition is beyond his competence to the appropriate branch of the hospital service to get the required treatment But no special reference is made to tuberculosis, all cases beyond the competence of the practitioner service being lumped together for reference to the specialist branches

In many perhaps most tuberculosis schemes before the National Health Service Act came into force, general practitioners were invited to refer suspicious or doubtful cases of tuberculosis to the tuberculosis dispensary before making notification The tuberculosis officer (now chest physician—a stupid title when tuberculosis is a systemic disease) after examining a suspect gave in his written report to the general practitioner, advice as to the need to notify to the medical officer of health By this procedure, in some parts of England, for example Lancashire, over 90% of new cases were examined and "screened" by the tuberculosis officers *before* notification This step in practice corresponded in part to "intimation" Has anything like this figure of 90% become general in England, Wales, and Scotland? The answer to this question would appear to govern the urgency or importance of making "intimation" a statutory procedure

Would medical practitioners find it a convenience to have provision on the all purpose notification form for an intimation to be sent? This could be introduced on the notification form as an alternative to and alongside the Form of Certificate of Notification as is shown below (In Northern Ireland there are two sheets A and B which I understand led to some confusion at first)

FIRST SCHEDULE

Form of Certificate	*Alternatively* *Form of Intimation*
To the Medical Officer of Health of ______	To the area Tuberculosis Physician Dr ______
I hereby certify and declare that in my opinion	I have examined ______
(1) ______	of ______
of (2) ______	and suspect the patient may be suffering from Respiratory/Non-respiratory Tuberculosis
is suffering from tuberculosis	
Age ______ Sex ______ Occupation or description ______	Age ______ Sex ______ Occupation ______
Organ or part affected ______	Medical condition ______
Place of ordinary residence if different from that at (2) above ______	I would like this patient to be specially examined for tuberculosis and a confidential report sent to me Attendance at the Clinic can/cannot be arranged

CELLOPHANE ENVELOPES FOR A SYRINGE SERVICE

SIR,—The specially stout 'Cellophane' envelopes devised by Dr J E McCartney (March 3, p 509) provide, as he says, "a simple, cheap, and disposable container for the syringe"

There are two disadvantages in the use of such envelopes The wrapper provides for the reasonably safe outward transit of these sterile syringes, but on the return journey to the laboratory the syringes lack the protection afforded by test tubes or aluminium tubes, and the saving under all heads, is more than offset by the increased breakage rate in syringes.

The other disadvantage is that Messrs Clear View Ltd can only guarantee supplies of these envelopes in thinner quality there is no hope (meantime, we presume) of them stocking the thicker film We have tried the thinner envelopes and find them quite suitable, but more liable to be cracked on handling even after being allowed to become pliable

From our experience of running a syringe service, for a few years, we are of opinion that the most suitable containers are aluminium screw-capped tubes, with smaller aluminium tubes to take the needle and act as a distance-piece to support the syringe assembly in these screw capped tubes Unfortunately, aluminium too is in short supply at present—but we are well served by stout 'Pyrex' test tubes (with rims on which the syringe rests) which, although dearer than ordinary test tubes, are of long life and are easily cleaned

North Middlesex Hospital London N 18

J F HEGGIE

VACCINATION AGAINST SMALLPOX

SIR,—In his article entitled "Does Vaccination help to spread Smallpox ?" (Jan 13), Dr Millard is asking a question based on some observations which have apparently led him to believe that the answer is in the affirmative But if this is so, it is not the fault of the vaccination itself but of the lax way in which vaccination has been regarded and enforced in the United Kingdom The recent abolition of compulsory vaccination has only served to make the public even more complacent This would perhaps be justifiable if there were no risk of the introduction of the disease from outside the country , but almost every epidemic in recent years has been started in this way, and the increasing use of air travel has increased the risk, not diminished it The examples given by Dr Millard himself bear this out "a seaman" (1912, Newhaven), "a de mobbed soldier" (1918, Croydon), "a seaman" (1921, New Forest), "an Asian seaman" (the recent outbreak in Glasgow) In this last case, the man was said to be "well vaccinated" If this was so, one must admit failure No one has claimed 100% protection for vaccination, but one failure is not sufficient to condemn the whole system

It would seem that there are two courses open to the health authorities in the U K Either they must see that the public is properly vaccinated, or else they must see that all persons entering the country have been recently vaccinated This latter provision is obviously the simpler, and is only what is already required by most other countries of the world

Traditional British policy has always been against any sort of "quarantine laws," on the assumption that if a country sees to its own internal hygiene it need not fear the introduction of disease from without This is no doubt true of many of the international diseases, particularly cholera and yellow fever , but it is dangerous to generalise and apply this line of thought to smallpox, which is quite unaffected by "hygiene" of the ordinary sort The only "hygiene" which would protect the country from the introduction of smallpox from outside is wholesale compulsory and repeated vaccination

In any case what is the objection to vaccination ? If done in infancy it is perfectly harmless, within the limits of human fallibility The only way to enforce vaccination is to see that the person has something to lose if he is not vaccinated Travellers can be made to comply by being refused admission to the country Parents can be made to comply by refusing their children admission to school unless vaccinated, as is done in America In this way the objectionable and "un British" prosecution of offenders would be done away with

It would be a great pity if opinions such as Dr Millard's were allowed to hamper the already difficult work of those health authorities who appreciate the value of vaccination as a well tried and tested method of protection

South African Native College
Fort Hare Cape Province

W NORMAN TAYLOR
Professor of Hygiene

SIR,—Dr Millard desires a revision of the present status of vaccination against smallpox on the following grounds

1 Vaccination is responsible for mild and modified cases which escape detection and thus spread smallpox amongst the unvaccinated

2 Infant vaccination may lead to an increase in virulence of the strain of the disease

Smallpox in vaccinated persons is almost always mild and modified and may ordinarily be mistaken for varicella However, correct diagnosis, even in cases which arouse only the slightest suspicion, should present no difficulty, particularly in the United Kingdom with its highly organised Public Health Laboratory Service Van Rooyen and Illingworth have pointed out that elementary bodies of variola virus can be demonstrated in less than half an hour from stained tissue scrapings obtained even from the "bathing drawers" rash which appears as early as the 2nd day of the disease I quite realise that Dr Millard may have in mind those ambulant patients who scarcely feel ill and spread infection during their perambulations , but such a contingency only strengthens the plea for the regular and systematic protection of the whole population at risk It does not appear to be a sound proposition to have the whole community highly susceptible, so that cases of smallpox when they do occur will be severe and thus easily detected The occurrence of such mild and missed cases can obviously never be ruled out, particularly at ports, and the only way of limiting mischief from them is to maintain a high level of herd immunity at places which are possibly at risk

Dr Millard states that while vaccination benefits the individual it is detrimental to the community This antagonism will not arise when the whole community enjoys the same level of protection, by mass vaccination That mass vaccination effects a diminution in the incidence of smallpox in addition to a striking reduction in mortality is supported by statistical data from Palestine, China, and India Perhaps the best evidence in this respect is furnished by the striking relation that can be observed between the incidence of smallpox and the different vaccination laws that prevail in the various States in the U S A

Dr Millard advances the theory that infant vaccination may tend to increase the severity of the strain of the disease He implies thereby, that the present indigenous disease "alastrim" may be permanently displaced by smallpox as a result of a continuous process of transmission of infection from mild cases of smallpox amongst the vaccinated to the unvaccinated Vaccination has been prevalent in the United Kingdom for the last so many years, and for several decades its practice has been concurrent with the process of displacement of smallpox by alastrim It is hard to see how vaccination can now be considered to lead to a reversal of the process On the other hand one should rather be alert for possible repercussions of the recent relaxation of vaccination laws

His observation that smallpox has not been eradicated from India is quite correct That, as he rightly recognises, is due to the high virulence of the virus, protection against which demands a very high level of immunity The belief among a very large section of the population that vaccination in infancy protects for life hampers revaccination work, which requires a large measure of public cooperation The result is that there is always a large proportion of susceptible population which contributes among other factors to the periodic epidemics of smallpox in this country

Dr Millard's suggestion for the implantation of alastrim in India with the idea of its elbowing out smallpox is indeed a fascinating one He thinks that for a start inoculation with alastrim virus instead of vaccinia (vaccination) may be undertaken in a town or district and that even more heroic measures would be justified The situation in the United Kingdom has no doubt prompted this suggestion The gradual and striking reduction in the incidence of smallpox in the U S A from 42,679 in 1930 to 4346 in 1934 without any nation wide vaccination efforts has also led to the speculation that a mild strain of smallpox which often goes undetected is rapidly immunising large numbers of persons It is however a moot point whether such substitution is possible or desirable except through purely natural forces Alastrim is after all a disease whose symptoms, though mild, are not unlike those of smallpox —e g , fever with generalised eruption and constitutional disturbance Mass inoculation, in however small an area, with a virus which makes itself felt so appreciably, is certainly not a measure one can take with equanimity

Further the difficulty of maintaining a sufficient stock of alastrim virus is too apparent, for it can with certainty be transmitted only to monkeys, and there is no guarantee that with continued passage in embryonated eggs it will breed true.

I feel I should conclude by quoting Dr Frederick F. Russell's contribution to a symposium held at the Harvard School of Public Health in 1929:

> "A community is not a stationary group; its age composition may have a certain stability but it is maintained by constant accessions and constant deaths; and it should be looked upon not as fixed group but as a parade, steadily and regularly marching past. To maintain a constant level of immunity against smallpox in such a group, vaccination must be done regularly on all newcomers, if possible in the first year of life; and revaccination must be carried out on all school children. To this activity there should never be an end until the whole world is vaccinated, and smallpox completely eradicated; so long as this disease lurks in some backward region, it may reappear in epidemic form unless all civilized countries continue to vaccinate each new generation."

Vaccine Institute,
Belgaum, India. R. S. RAO.

WILL WE NEVER LEARN?

SIR,—Much heart searching must follow Sir Heneage Ogilvie's letter in your last issue. I refer more particularly to the first part of his mixed grill. Every young doctor nowadays is a potential soldier, and if he is surgically inclined, and war provides the opportunity, he will be used in one part of the chain that stretches from the regimental aid post, across continents and seas, to the home hospital. Appointing a consulting surgeon to a group in the field is not the answer, be he even a marathon runner. Reading the surgical history of past wars is not a practical proposition. Many factors go to the making of a successful surgical set up in any campaign, and the terrain will always modify the pattern. Medical directives and surgical pocket books are a boon, and an O i/c division who gives his teams regular surgical anatomy talks is a treasure, &c. "Will we never learn?" The answer is "Yes, if we are taught." In every medical teaching centre there should be a chair of military surgery, and for choice it should be filled by one who has actually operated in the field.

Sir Heneage Ogilvie is in the highest regard in the highest of places, and is the very man to initiate the implementation of such a project.

Longtown, Cumberland. R. RUTHERFORD,
Hon. Colonel, T.A.

SIR,—Having had the honour of serving with Sir Heneage Ogilvie in the first world war, I would welcome the opportunity of condemning with him the "have a go" mentality. As a radiologist one has had unique opportunities for watching most of the game. A problem has faced the master surgeon; he has studied it carefully in the light of his past experience and that of his colleagues; and, as a senior, after much patience, he has devised a method of attack and with great skill has carried it through successfully. So successfully that he has tried to repeat it with other cases; but whether because no two cases are the same, or because subsequent ones have not been subjected to the same critical inquiry, the results have sometimes been so disappointing that he has abandoned it. Long after this, men who have heard of the success of the original case, but do not possess the same knowledge or have not even acquired the necessary skill continue to use the method, apparently hoping that one day they will be rewarded.

No more glaring instance of the lack of thought for the patient has been witnessed than in the removal of foreign bodies. We established in the first war that with care radiological localisation could be so accurate that surgical removal of the foreign body could be done with little more time than was required to make the necessary incision. It was so accurate, and the actual removal required so little skill, that the sister of one department I serve received a notice from the surgeon: "Please do not put any localising mark on the skin—it spoils our fun."

I much regret that radiography is responsible for much of this "have a go" activity; without it more attention would have to be paid to the patient and much incitement would be missing.

But this type of activity is not only applicable to surgeons. Sir James Paget described his case of osteitis deformans only after careful clinical observations throughout more than 20 years; and his description was so complete that no important contribution has been made since, though many thousands of cases of Paget's disease have been subjected to multiple investigations, employing surgery, biochemistry, physiotherapy, and radiology merely because various workers had described tests, of no value to the treatment, which yielded positive and negative results. The fact that a writer of repute has described a particular finding—something which one need but remember—seems to lead every man who has such a case to apply the test described, no matter how inferior his means for applying it, or how able he is in its interpretation; and should he obtain a different result he records it and incites others to check.

The answer to Sir Heneage's question appears to be "No" since a number of our leading teachers in all spheres of medicine have written similar criticism. Perhaps none more forcibly than Sir James Walton[1] in the words: "Perhaps in the lifetime of many of you these marvellously skilled operations will cease to be performed, and will be regarded as curiosities of the past."

With apologies to the memory of Ruskin I would say that in former days men used their art to remove the cause of pain, but more recently they have used the cause of pain to show off their art—unfortunately not always to the benefit of the patient but at great expense to the community.

Birmingham. JAMES F. BRAILSFORD.

SIR,—Sir Heneage Ogilvie has come charging down from Mount Olympus, over which he appears to enjoy the sole shooting rights, in an attempt to drive me from the small holding I have tried to establish in one of the foot hills.

His attack is also directed at a young naval surgeon doing his unattractive duty off the coast of Korea. The Senior Service may remain silent, but not I.

We two unmentionable men are accused of writing articles on subjects about which we know little and have thought less. We are lamentably lacking in experience and totally unfamiliar with what is known as the literature.

How does a surgeon gain his experience? By obtaining surgical registrarships and working hard under the direction of men who are older and wiser than he. During my early years I held five such registrarships, two of them in teaching hospitals other than my own. I assisted at hundreds of gastrectomies and I had access to the records of hundreds more. It was this very experience that sent me in search of a safer way of dealing with the duodenal ulcer.

The search took me to France, Switzerland, Germany, Austria, and the United States of America, not as an honoured guest or in an official capacity but as a private person paying my own expenses and spending my own spare time. Sir Heneage underestimates my diligence if he imagines that I could miss Manchester. After enjoying the stimulating and cordial hospitality of Mr Wilson Hey I returned to London more eager than ever to employ the operation which in his hands and in mine gave such promising results

---

[1] Brit. med. J. 1950, i, 306.

Am I so ignorant of the literature? I fear I may be, but I do try to keep myself informed about a number of things For many years I have read surgical journals in three foreign languages as well as a carefully selected series from both sides of the Atlantic, many of which are written in English Before the war I made translations from the foreign publications and condensed them for publication in one of our well known weekly medical journals But I must admit that I completely missed the series of one unsatisfactory case mentioned in the *British Medical Journal* in 1947 and I have not read of the Madras disasters But then I am handicapped by having no Telegu

Sir Heneage does not like my article, and he has a perfect right to say so, but to suggest that it is a casual contribution or an exhibition of flippant ignorance is just a little discourteous Now that I have gained my majority as a fellow of the college I rather dislike being rated as an irresponsible adolescent by the house master

My article is an interim report If in another ten years another tale must be told, be sure that I shall tell it If, in the meantime, I am in a minority, I shall not mind The kindly earth of Kirkcudbright has for centuries concealed the broken bones of men who dared to disagree with their powerful neighbours, and they all bore the name of your humble contributor,

London, W 1 EDWARD MACLELLAN

THE INVESTIGATION OF SUGAR TOLERANCE

SIR,—I was most interested to read Dr Lawrence's letter of Feb 24 It is true that the isolated 2 hour blood-sugar level will not give a precise diagnosis in all cases of symptomless glycosuria, but it will show whether or not the glycosuria results from reduced sugar tolerance The differentiation of renal glycosuria from lag storage as the cause of glycosuria will demand additional blood sugar determinations if it is considered necessary to distinguish between them Starvation and thyrotoxicosis both cause reduced sugar tolerance, with elevation of the 2 hour blood sugar level The fasting blood sugar may be normal or raised in such cases, and thus may not assist in making a diagnosis from diabetes mellitus

It will be generally agreed that the results of any method of testing for sugar tolerance must be interpreted in the light of the information obtained from interrogating and examining the patient

Department of Medicine
Middlesex Hospital London, W 1 JOHN FRIEND

FOOD AND ENERGY

SIR,—*The following quotation*[1] *appears to need no* comment

"DIET AND ENERGY"

"There is no doubt that diet plays an important part in enabling the American worker to work faster and to keep up the effort The question was discussed with several operators and it was estimated that the American worker had in the course of a week

Meat	3 lb to 4 lb
Eggs	12 to 18
Milk	5 to 6 pints
Fats	Four times as much as the English worker with a good supply of fruit juices either in concentrated form or as fresh fruit

Here we might mention that members of the Team enjoyed much greater energy as the weeks went by and were able to do their arduous job of walking round factories all day without fatigue In addition they were able to follow without difficulty the American way of life and carry on with the minimum of sleep"

London W 1 FRANKLIN BICKNELL

Parliament

QUESTION TIME

New R A F "T A B T" Vaccine

Mr P L WELLS asked the Secretary of State for Air what was the nature of the new kind of inoculation proposed to be used at certain Royal Air Force camps.—Mr ARTHUR HENDERSON replied The "new" inoculation introduced by the R.A.F is a combination of two well tried immunising agents, T.A.B vaccine and anti tetanus toxoid, it is named T A B T Two injections are given initially, at a few weeks' interval, and one injection annually thereafter or on first arrival in an overseas command No further proof has been sought of the proven efficacy of T A B vaccine or tetanus toxoid, and the medical authorities are satisfied that they can be given together without harm or loss of effect No bad results have been reported from the use of this substance. All ranks are reminded periodically that vaccination and all inoculations are voluntary

Influenza and Sickness Benefit Claims

Replying to Mr SOMERVILLE HASTINGS Dr EDITH SUMMERSKILL, Minister of National Insurance, said that her department had had the heaviest load of sickness benefit claims in its short history in respect of the influenza epidemic. The local offices and the central office, Newcastle, had stood up to the test well During the first six weeks of the year the number of new claims to sickness benefit was almost double the figure for the same period last year—just over 2,100,000, compared with about 1,100,000 At one time some 1,500,000 persons—1 in 15 of the insured population—were claiming sickness benefit

Tuberculosis Beds in Switzerland

Mr HENDERSON STEWART asked the Secretary of State for Scotland if he would make a further statement on the provision of beds in Swiss sanatoria for Scottish tuberculous patients —Miss MARGARET HERBISON replied Exploratory discussions are now proceeding with the authorities of certain Swiss sanatoria as to the charges they would make for the treatment of patients from this country These discussions will be concluded shortly and I hope it will then be possible for the Government to reach a final decision

Hospital Costs

Colonel LEONARD ROPNER asked the Minister of Health if, with a view to stimulating efficiency and economy in the hospital services, he was preparing a detailed analysis of hospital costs under the National Health Service —Mr ARTHUR BLENKINSOP replied that a uniform system for analysing hospital costs in some detail had been introduced for the first time this year and would relate to the year 1950–51 as a whole Broadly the return would be in a similar form to that issued by the Department of Health in Scotland The Ministry were still discussing with the Treasury the best way in which this information could be made available to Parliament and the public at a suitable time

Corporal Punishment in Approved Schools

Mr R W SORENSEN asked the Home Secretary what consultation with psychologists, specialists in juvenile delinquency, and other authorities had taken place in his department during recent years in respect of appropriate discipline and punishment in remand homes and approved schools; whether particular attention had been given to the incidence of corporal punishment both as a deterrent and with regard to its alleged remedial effect on individual characters, and to what extent the experience and example of other countries in regard to this problem and the fact that corporal punishment was not administered in similar institutions in many countries had been examined in relationship to modifications of our own practice —Mr CHUTER EDE replied Methods of discipline and punishment, including corporal punishment, in remand homes and approved schools are kept under constant review, as regards their suitability and the extent of their use, by the inspectorate of the Home Office children's department, which includes psychiatrists, in consultation as necessary with the managers and staff of the homes and schools, who have extensive knowledge and experience of the problems presented by young offenders A psychiatrist, and persons with wide experience of dealing with delinquents, are among the members of the committee which I appointed in November 1948, to review punishments in prisons, Borstal institutions, approved schools and remand homes. The committee's report dealing with approved schools and remand homes is expected to be available shortly

Mr SORENSEN Are there not numbers of psychiatrists and others who deprecate excessive corporal punishment?—Mr EDE The committee appointed as a result of an undertaking given during the passing of the Criminal Justice Act, 1948 has been fully investigating this matter Psychiatrists differ even more than doctors

Births in Prisons

In answer to a question, Mr EDE said that since the Order relating to births in prisons came into force on Dec 27 15 children had been born in His Majesty's prisons and borstals in England and Wales, and 92 women had been confined in outside hospitals It was the practice for every woman to be asked, well before her confinement, whether she preferred to be removed to an outside hospital for the confinement, and if she did, suitable arrangements were made In a few cases, for instance, where labour was precipitate, it had not been possible to effect the removal in time

Public Health

Prescribed Diseases

UNDER the National Insurance (Industrial Injuries) (Prescribed Diseases) Amendment (no 2) Regulations, 1951, the Minister of National Insurance extends insurance under the National Insurance (Industrial Injuries) Act, 1946, against byssinosis to people employed in certain rooms in waste-cotton factories. The regulations also provide for payment of disablement and death benefit from the date when the regulations came into operation (March 1) in the case of people covered by the regulations who suffered or died from the disease before this date

New regulations extending insurance under the same Act to tuberculosis in nurses and certain others insurably employed in occupations involving close and frequent contact with tuberculous infection are discussed on p 573

Influenza

During the week ended Feb 24 deaths from influenza in the great towns of England and Wales decreased to 15 3 per million population from 23 7 per million in the previous week. For the great towns grouped regionally the influenza death-rate decreased everywhere except in the northern and eastern regions, where slight increases were recorded The proportion of influenza deaths in patients aged 55 or over was 89 3%, compared with 88 8% in the previous week. In the whole of England and Wales new claims to sickness benefit in the week ended Feb 20 numbered 161,600, compared with 200,300 in the previous week

Notes and News

NEGOTIATIONS WITH THE MINISTER

ON Feb 28 a deputation appointed by the General Medical Services Committee met the Minister of Health to discuss the Ministry's latest proposals on the remuneration of general practitioners No statement was issued after the meeting The members of the deputation were Dr S Wand, Dr W Jope, Dr E A Gregg, Dr H H D Sutherland, Dr A Campbell, Dr H G Dain, Dr A B Davies, Dr F Gray, and Dr W M Knox, with the actuary, Mr R C Simmonds, F I A An emergency meeting of the committee was held on March 6, and a special conference of representatives of medical committees will take place on March 29

"Z" RESERVISTS

THE Central Medical War Committee and the Scottish Central Medical War Committee have been informed that they may consider appeals from doctors who, as members of "Z" Reserve, receive a warning notice of recall for 15 days' training and consider that their withdrawal for this period would jeopardise the civil medical services in their areas Appeals should be addressed to the secretary of the Central Medical War Committee at B M A House, Tavistock Square, London, W C 1, or, in Scotland, to the secretary of the Scottish Central Medical War Committee, at 7, Drumsheugh Gardens, Edinburgh These committees cannot deal with any question of personal hardship, which is a matter for the Service department

REBIRTH OF THE MIDDLESEX ARCHIVES

THE *Archives of the Middlesex Hospital* died in 1916, at the age of twelve, killed by the first world war It has now been restored to life under the editorship of Dr Douglas McAlpine, and we wish it long life and prosperity Mr Victor Bonney, in the introduction, reminds us of the achievements of its first years, when it carried Sampson Handley's classical papers on parietal dissemination of mammary carcinoma, William Pasteur's original observations on massive collapse of the lung after abdominal operations, and Bonney's own study of the connective tissue in carcinoma, as well as many other notable contributions The hope of the new editor and his committee is to encourage the younger members of the Middlesex staff and the registrars to write up interesting cases and make original observations At the same time, every number will contain one or two articles of direct interest to the general practitioner

The first number of the new *Archives* lives up to these intentions The six articles in it deal with arteriography of the abdominal aorta, atypical abdominal tuberculosis simulating myeloid leukæmia, toxoplasmosis, disorders of the cervical intervertebral discs reconstitution of the vas deferens after a sterilising operation, and "chronic mastitis—a non existent disease" The lively text, the splendid illustrations, and the fine glossy paper combine to lure the reader on

GUY'S HOSPITAL DENTAL SCHOOL

THE annual clinical meeting of Guy's Hospital Dental School was held on March 3 Although this year there was nothing comparable to the colour television of the last meeting, all departments combined to present an excellent programme of demonstrations and clinical cases The endeavour was to show the many and divers aspects of the present dental curriculum and to emphasise the close relation between dentistry and general medicine

From the many demonstrations it is only possible to single out a few that have medical as well as dental interest An exhibit by Mr A Bulleid and Mr C W T Shuttleworth, of the department of preventive dentistry was concerned with the use of the various antibiotics in the treatment of apical infections Penicillin has so far proved the most effective although there has been an unfortunate increase in the number of penicillin resistant strains of bacteria found in the mouth It is now a routine practice to administer a massive parenteral dose of procaine penicillin before extracting impacted wisdom teeth Mr Bulleid emphasised the importance of determining the erythrocyte sedimentation rate before condemning teeth with chronic apical infection or those surrounded by chronic pyorrhœa, the E S R is never increased in chronic dental conditions but only in those which are acute A further point mentioned was the necessity of controlling the treatment of gum lesions with penicillin by means of gum smears, since clinical abnormality disappears long before the bacterial picture returns to normal Work is still in progress on the various methods of caries control —topical applications of sodium fluoride, ammonium urea toothpowders, and Gottlieb's enamel impregnation method—and though most of the methods show moderately good results, it is still too soon for definite statistical appraisal of their value Slides and specimens of some of the rarer oral diseases were on view in the department of dental medicine, and this department also demonstrated the determination of the organic content of enamel by paper chromatography —a method of importance now that caries is generally held to begin as a process of proteolysis rather than of decalcification Orthodontic treatment is now being used more and more in the postoperative treatment of cleft palate and hare lip, and the children's department arranged a demonstration to show what can be achieved in the way of cosmetic and functional improvement During the morning session Mr N L Eckhoff performed an epithelial inlay operation for the improvement of a deformity after a hare lip repair Some examples of the work of the upper respiratory tract unit were also shown, during the treatment of malocclusion and oral deformities this unit investigates the whole medical history and the social background of the patient One of the dental advances of the year has been the introduction of self polymerising acrylic resins for restorations in anterior teeth, the technique was demonstrated by Mr J W McLean

* * *

University of Oxford

On Feb 24 the degree of D M was conferred on R W Parnell and Sheila R Tangye

University of Cambridge

At a recent examination for the degree of M CHIR the following were successful

T G E Loosemore, G M Lunn J R Thompson, J F R Withycombe

University of London

The William Julius Mickle fellowship for 1950–51 has been awarded to Mr R C Brock surgeon to Guy's Hospital and the Brompton Hospital, London

University of Glasgow

In connection with its 500th anniversary celebrations the university is conferring over 50 honorary degrees The medical graduands from this country are Prof E D Adrian, O M, Prof H F Humphreys, F D S, Prof Dorothy Russell, and Sir John Parkinson Those from overseas are Prof Evarts Graham (Washington University), Prof J M Holst (Oslo University), Prof B A Houssay (formerly of Buenos Aires University) Prof René Sand (Brussels University), and Prof G H Whipple (Rochester University)

Royal College of Obstetricians and Gynæcologists

A Leverhulme research scholarship (£250) is offered for research into problems connected with obstetrics and/or gynæcology It may be held simultaneously with another appointment Forms of application may be had from the secretary of the college 58, Queen Anne Street, London, W 1, and should be returned by July 1

A prize (£50) will be awarded by the council of the college in 1952 for the best original work on the Improvement of Forceps Deliveries Further particulars may be had from the secretary of the college

International Congress of Physical Medicine

This congress will be held in London from July 14 to 19, 1952, under the presidency of Lord Horder Further particulars may be had from Dr A C Boyle, hon secretary, 45, Lincoln's Inn Fields, W C 2

Use of Radioactive Materials

The Ministry of Supply has set up an atomic energy school to teach workers in industrial and medical laboratories how to use radioactive materials The first course, lasting six weeks, begins at the Atomic Energy Research Establishment at Harwell on April 2 Twelve students will be accepted on each course, which after the first, will last for four weeks The second and third courses are expected to begin on May 15 and June 18 Further particulars are available from Dr J E Johnston Isotope Division A E R E, Harwell, Berks

Central Council for Health Education

Dr Robert Sutherland, for the past eight years medical adviser and secretary to the council, has resigned to take up an appointment as senior lecturer in preventive medicine and public health at the University of Leeds

Postgraduate Work in Plastic Surgery

Mr R J V Battle will be at the Royal College of Surgeons on April 5 and on following Thursdays from 2 30 P.M. to 3 P M to advise graduates from this country and overseas on postgraduate studies in plastic surgery He will try as far as possible to find suitable clinical vacancies Further details may be had from Mr. W F Davis, secretary of the postgraduate bureau Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2,

Courses in Hospital Administration

A course which will last about two years, will start in October at the Hospital Administrative Staff College of King Edward s Hospital Fund. Candidates, who must hold an appointment in the hospital service, will be selected by a special panel set up by the Fund, and the Ministry of Health has agreed that study leave with pay may be granted to the candidates selected Although no strict age limit will be imposed it is expected that candidates will be over 25 and under 35 Application forms may be had from the principal of the college, 2, Palace Court, Bayswater, London W 2

Royal Sanitary Institute

Lord Hesketh will preside over the health congress of the institute, which is to be held at Southport from April 23 to 27 Medical speakers will include Sir Henry Cohen and Dr E T Conybeare (The Rheumatic Diseases), Dr A. Torrie (Placement of Children for Adoption), Prof A. V Neale Dr Winifred Kane, and Dr R W Eldridge (Relationship of the Child Welfare Officer and the School Medical Officer to the National Health Service), Dr D W Horn (Cerebrospinal Fever), Dr H N Davies (Tuberculosis), Prof G P Crowden (Coöperation Between Medical Science and Engineering in Industrial Hygiene) Dr J N Morris (Industrial Health What is it we are Trying to Do ?)

Colonial Appointment

Dr Samuel Layinka Ayodeji Manuwa, whose appointment as director of medical services, Nigeria, was lately announced, has been a member of the West African Medical Service since 1927

Dr Manuwa was born in 1903 at Porogun Ljubu Ode Nigeria, and he was educated at the C.M.S grammar school Lagos King's College Lagos and Edinburgh University He graduated M.B at Edinburgh in 1926 The same year he also took the D T.M at Liverpool and the L.M at Dublin In 1927 he joined the Colonial Medical Service as junior medical officer in Nigeria He proceeded to his M D in 1934 also taking the D T.H. at Liverpool. Two years later he obtained the F R.C.S.E In 1944 he was appointed a surgical specialist in the Colonial Medical Service and in 1947 senior specialist In 1948 he was promoted to be deputy director of medical services (regional) He has published papers on Hernia in the West African Negro and Chronic Splenomegaly in West Africa. He was appointed O B E in 1948

Anti-tuberculosis Centre at Istanbul

The new W H.O anti tuberculosis centre, built by the Turkish government at a cost of $130 000 was opened in Istanbul on Feb 17 The centre has been working in temporary premises since its foundation last June, and at the opening of the new headquarters several speakers stressed the value of the work done by W H O in Turkey, where tuberculosis causes 40 000 deaths annually Dr Etienne Berthet director of the centre, recalled that its primary function was to train medical and health workers in modern anti tuberculosis methods and to create a unified organisation against the disease which would serve as a model for similar services elsewhere Dr J B McDougall chief of the tuberculosis section of W.H.O explained that the staff of the centre, consisting of a French tuberculosis specialist an English X ray technician, and a French nurse, had in eight months given instruction to nearly 300 Turkish doctors and nurses In addition 10 000 X ray examinations had been made, 8000 people tested with tuberculin and 3000 vaccinated against tuberculosis A second W.H.O anti tuberculosis centre has already been established in New Delhi and others are in course of preparation for Thailand, El Salvador, Burma, Ceylon, and Pakistan

International Hæmophilia Society

The annual general meeting of this society will be held at the Society for Visiting Scientists, 5, Old Burlington Street London, W 1, on Sunday, March 11, at 2 30 P.M.

Ophthalmological Society of the United Kingdom

The annual congress of this society will be held at 1 Wimpole Street, London, W 1, on Thursday, Friday and Saturday March 29 30, and 31, under the presidency of Mr M H Whiting who will give an address on Surgical Treatment of Rodent Ulcers near the Eye Further particulars may be had from the hon secretary, 45, Lincoln s Inn Fields, W C 2

The Minister on Joint Consultation

Speaking at Darlington on Feb 25, Mr H A Marquand, Minister of Health, remarked 'I am a profound believer in joint consultation in industry, and I want to encourage and develop joint consultation to the maximum extent in the health service I want everyone in the service—doctor nurse, physiotherapist, welfare officer, clerk, or whatever they may be—to feel that they are partners in this great national enterprise, that their ideas and suggestions are welcomed and considered, that their coöperation is highly valued "

Dinner to Sir William Kelsey Fry

The Duke of Gloucester was present at a dinner held at the Royal College of Surgeons of England on Feb 21, to give friends and colleagues the opportunity of congratulating Sir William Kelsey Fry on his knighthood Sir William s health coupled with that of Lady Fry, was proposed by Mr Arthur Bulleid, Air Commodore G A. Ballantyne, and Mr C W Roberts Sir Cecil Wakeley, P.R C S who had been in the chair, presented Sir William with an album containing the signatures of those present

Proposal for Normal Confinements at Home

The London Local Medical Committee has resolved that steps to remedy the shortage of hospital beds ' should include an instruction to hospitals in the London area to see that normal maternity cases are not admitted to hospital except where a responsible person certifies that home conditions make hospital confinement essential Dr Frank Gray, secretary of the committee, said ' Three quarters of all births in the London area are now taking place in hospitals and other institutions A very large number of these could just as well take place at home There is no doubt that a considerable number of people would still be alive today if only beds could have been found for them in hospitals '

Kingston Victoria Hospital

Mr H A Marquand, Minister of Health in a letter to Mr J A. Boyd Carpenter, M.P for Kingston, Surrey, upholds the decision of the South west Metropolitan Regional Hospital Board to convert Kingston Victoria Hospital from a general practitioner hospital into a gynæcological unit " I am quite clear, writes Mr Marquand, that the balance of advantage very definitely lies with the regional board s decision. It is made, I need hardly remind you, after receiving expert medical as well as lay advice ' Mr Marquand goes on to remark that he is alive to the importance of general practitioners in the area having proper alternative hospital resources for their ordinary work, and also every possible facility for following up their own patients when these come under the care of specialists in hospital The proposed arrangements at the Surbiton annexe should he thinks, give reasonable alternative beds for ordinary general practitioner work, particularly if the doctors themselves will coöperate with the board in settling and carrying out some of the details of the arrangement of the new accommodation at their hospital " Mr Marquand has been assured by the chairman of the regional board that the board intends to see that clinical assistantships are offered to the general practitioners and also that the practitioners are given every encouragement to keep in contact with their patients and their treatment when these patients are in the hands of specialists in the hospitals

A statement issued after a meeting on March 5, of the combined medical board and lay committee of Kingston Victoria Hospital contended that this letter ignored the main issue—the provision of equivalent facilities for both patients and doctors—which had been put by a deputation seen by the Minister The committee once again pressed for an impartial public inquiry

Prospect of War

A meeting, sponsored by the writers of the letter on this subject in our issue of Jan 20 (p 170) and other colleagues, will be held at 45, Russell Square, London, W C 1, on Friday, March 16, at 8 P M All doctors interested in the preservation of peace are invited to attend and take part in the discussion

British Medical Association

Dr A W S Sichel, president of the Medical Association of South Africa since 1945, has been elected president of the British Medical Association for 1951–52 Dr Sichel, who is a graduate of Edinburgh University, has been a member of the B.M.A since 1920 The annual meeting of the B M A, which is to be held in London this year, was at one time to have taken place in Johannesburg

Uncertificated Almoners

The Institute of Almoners has opened a supplementary register for some of the almoners employed in the National Health Service who do not hold the institute's own certificate of qualification.

The supplementary register will be open from March 1 to Dec 31 1951 Those applying for admission must be over 30 years of age engaged in medicosocial work in hospital, and known as almoner both at the time of application and continuously for 3 years before July 5 1948 Those admitted to the supplementary register will be entitled to apply for a special category of membership of the institute which will bring them under the ægis of the institute in all professional matters including negotiations for salaries and conditions of service

Foot Health Educational Bureau

This bureau has now formed an advisory panel which includes representatives from medicine, surgery, chiropody, and physical education, and members from the technical and educational sections of the shoe and leather trades Brigadier G S Parkinson is chairman of the panel, and other medical members are Mr S L Higgs, Mr S A S Malkin, Dr R Piper, Mr T T Stamm

Medical Congress at Turin

An international health exhibition with international medical surgical meetings will be held in Turin from May 30 to June 12 These events have been arranged by staff of the *Minerva Medica* and they are sponsored by the Italian Medical Association Prof A M Dogliotti, director of the Turin Surgical Clinic, is chairman of the general committee Further information may be had from the general secretary Prof S Teneff, Palazzo delle Esposizioni al Valentino, Turin, Italy

---

Prof G F Marrian, F R S, is visiting France, under the auspices of the British Council, to lecture to the medical faculties of Paris, Lyons, and Lille on the Metabolism of Progesterone

Prof Jimenez Dias director of the Institute of Medical Research Madrid, and professor of internal medicine in the University of Madrid, is visiting the United Kingdom, under the auspices of the British Council

---

CORRIGENDA

Micromanipulators —In our annotation of March 3 (p 516) the sentence (line 11) describing de Fonbrune's micromanipulator should read This apparatus has micropipettes controlled pneumatically by a 'joystick' operating three syringes containing air

The New Chambers's Encyclopædia —In our article last week (p 521) there were two major errors of omission We should have stated that the advisory editor responsible for the medical contributions was Dr Hugh Clegg, editor of the *British Medical Journal* And we should also have mentioned that subscription terms on which the new encyclopædia may be purchased will be forwarded on application to Messrs George Newnes, Tower House, Southampton Street, London W C 2

In announcing Dr Karl Bremer's appointment as South African minister of health and social welfare we attributed to him the qualifications of his son The new minister is a graduate of the University of London where he obtained the M B in 1909

I—The Surgeon's Activities
(G R G)

BOTH the scope and the length of surgical operations tend to increase with the progressive reduction in the risk to life from shock and loss of blood Advances in anæsthesia, surgical technique, and hæmostasis and a wiser use of blood-transfusion have combined to give surgeons a confidence which is dangerous unless equally progressive precautions are taken against infection for the risk of infection increases with the length and severity of an operation.

Advances in chemotherapy have provided new and most welcome antiseptic agents. Local and general chemotherapy is advisable as a precaution where there is special reason to fear infection, and general chemotherapy is imperative when clinical symptoms and signs indicate postoperative inflammation But for many reasons we should not permit any relaxation of effort to attain asepsis.[1]

The desire for safety is particularly strong in orthopædic work because grafts of autogenous tissues and the insertion of foreign substances increase the danger of uncontrolled infection, and make its outcome more than ordinarily disastrous These are convincing arguments for impeccable asepsis but the need for the highest possible standard of safety is even more pressing when it is remembered that many of the biggest orthopædic operations are not life saving measures but are undertaken with the limited aim of relieving discomfort or improving function It is greatly to the credit of Arbuthnot Lane, a pioneer in the adventure of operating for the betterment of function, that he was acutely aware of this responsibility, and not only adopted a meticulously careful technique but also emphasised its vital necessity He knew that greater initiative in surgical interference must be matched by greater vigilance.

Such prophylaxis includes the care of the patient as a whole and of the tissues of the wound in particular, and the prevention of infection by many procedures, including the good design and ventilation of the theatre Infection by pyogenic organisms does not necessarily cause appreciable inflammation, indeed pyogenic organisms are probably introduced, or fall, into clean wounds many times for every case in which suppuration appears

The care of the patient as a whole is not considered here, though it should be mentioned that his comfort, reassurance, and sleep during the days and nights before and after operation lessen shock and favour the vitality and recuperation of every part of his body So too do the steps taken to maintain the pressure and composition of his blood within normal limits during operation and thereafter

Suppuration of surgical wounds can be prevented

1 By taking the utmost care of the tissues so that they may retain their powers of resistance as fully as possible With this must be remembered accurate hæmostasis and temporary drainage of the wound whenever the subsequent formation of a hæmatoma is at all possible
2. By avoiding infection from the patient's own skin, from the hands of the surgeon and his assistants from instruments, gloves, gowns, mackintoshes, swabs sutures, and fluids, from the air and through soaked dressings or plaster-of paris

CARE OF THE TISSUES

The care of the tissues is of primary importance, for healthy vascular tissues are not easily infected, and their resistance to infection is favoured by good circulation and physical rest On the other hand, they are in danger if they have been bruised or dried by long exposure at operation, especially if they are subsequently devascularised from compression or disturbed by repeated movement

Unnecessary bruising can be avoided by thoughtful and sensitive technique Skill and delicacy of touch, clean sharp dissection without a single avoidable movement, swabbing by momentary pressure without a rub, exposure by design of incision rather than by powerful retraction, all these, with accurate hæmostasis, contribute to the safety and comfort of a wound. It is better to operate without a tourniquet when the operation can be carried out with equal accuracy, and when a tourniquet is used it should with few exceptions be removed for hæmostasis before the wound is closed, for long-continued compression is an undesirable and often ineffectual means of controlling subsequent bleeding, and a hæmatoma favours suppuration

Every stitch should be tied gently Deep skin stitches which include underlying tissues should not be tied tight enough to bring the skin together, the exact approximation of the skin is better achieved by the way the superficial stitches are inserted than by pulling them tight Finally in applying a bandage or plaster-of paris over the dressings great care should be given to the avoidance of undue compression Provision should always be made for subsequent swelling, and exact instructions given about the signs and symptoms of compression and the prompt action that should be taken for its relief. Postoperative plasters are better split vertically from top to bottom, and then held by a few bow ties of bandage, which can easily be untied and retied after the plaster case has been adjusted to give complete relief to the patient and to restore free circulation to the part

THE PATIENT'S SKIN

About a third of the population of this country carry *Staphylococcus aureus* in nose or skin, and the proportion

---

* Mr Girdlestone died on Dec. 30 1950

[1] In an address (unpublished) to the Association of Surgeons in 1949 Sir Hugh Cairns gave some personal experiences of operative infection In the first period (1927–38), when I was operating in two nursing homes as well as at a hospital where the theatre opened off the main corridor the incidence of fatal infection in operations for brain tumour was 2·7% In the second period (1938–44) when I worked in one air-conditioned theatre the incidence of fatal infection was 1% and the over all incidence of operative infection, including superficial wound infection and mild meningeal reactions was 4·4% In 1944 conditions otherwise being unchanged, we began insufflating penicillin sulphamethazine powder into all clean wounds as a routine prophylactic measure, and in the third period (1944–47) the incidence of operative infection fell from 4·4% to under 1% That there were no deaths from infection in this period cannot be attributed solely to prophylaxis, because when infections arose they were energetically treated with antibiotics.

Prospect of War

A meeting, sponsored by the writers of the letter on this subject in our issue of Jan 20 (p 170) and other colleagues, will be held at 45, Russell Square, London, W C 1, on Friday, March 16, at 8 P M All doctors interested in the preservation of peace are invited to attend and take part in the discussion

British Medical Association

Dr A W S Sichel, president of the Medical Association of South Africa since 1945, has been elected president of the British Medical Association for 1951–52 Dr Sichel, who is a graduate of Edinburgh University, has been a member of the B.M A since 1920 The annual meeting of the B M A, which is to be held in London this year, was at one time to have taken place in Johannesburg

Uncertificated Almoners

The Institute of Almoners has opened a supplementary register for some of the almoners employed in the National Health Service who do not hold the institute's own certificate of qualification.

The supplementary register will be open from March 1 to Dec 31 1951 Those applying for admission must be over 30 years of age engaged in medicosocial work in hospital and known as almoner both at the time of application and continuously for 3 years before July 5 1948 Those admitted to the supplementary register will be entitled to apply for a special category of membership of the institute which will bring them under the ægis of the institute in all professional matters including negotiations for salaries and conditions of service

Foot Health Educational Bureau

This bureau has now formed an advisory panel which includes representatives from medicine, surgery, chiropody, and physical education, and members from the technical and educational sections of the shoe and leather trades Brigadier G S Parkinson is chairman of the panel, and other medical members are Mr S L Higgs, Mr S A S Malkin, Dr R Piper, Mr T T Stamm

I.—The Surgeon's Activities

(G R G)

BOTH the scope and the length of surgical operations tend to increase with the progressive reduction in the risk to life from shock and loss of blood Advances in anæsthesia, surgical technique, and hæmostasis and a wiser use of blood transfusion have combined to give surgeons a confidence which is dangerous unless equally progressive precautions are taken against infection, for the risk of infection increases with the length and severity of an operation

Advances in chemotherapy have provided new and most welcome antiseptic agents Local and general chemotherapy is advisable as a precaution where there is special reason to fear infection, and general chemotherapy is imperative when clinical symptoms and signs indicate postoperative inflammation But for many reasons we should not permit any relaxation of effort to attain asepsis [1]

The desire for safety is particularly strong in orthopædic work because grafts of autogenous tissues and the insertion of foreign substances increase the danger of uncontrolled infection, and make its outcome more than ordinarily disastrous These are convincing arguments for impeccable asepsis, but the need for the highest possible standard of safety is even more pressing when it is remembered that many of the biggest orthopædic operations are not life saving measures but are undertaken with the limited aim of relieving discomfort or improving function It is greatly to the credit of Arbuthnot Lane, a pioneer in the adventure of operating for the betterment of function, that he was acutely aware of this responsibility, and not only adopted a meticulously careful technique but also emphasised its vital necessity He knew that greater initiative in surgical interference must be matched by greater vigilance

Such prophylaxis includes the care of the patient as a whole and of the tissues of the wound in particular, and the prevention of infection by many procedures, including the good design and ventilation of the theatre Infection by pyogenic organisms does not necessarily cause appreciable inflammation, indeed pyogenic organisms are probably introduced, or fall, into clean wounds many times for every case in which suppuration appears

The care of the patient as a whole is not considered here, though it should be mentioned that his comfort, reassurance, and sleep during the days and nights before and after operation lessen shock and favour the vitality and recuperation of every part of his body So too do the steps taken to maintain the pressure and composition of his blood within normal limits during operation and thereafter

Suppuration of surgical wounds can be prevented

1 By taking the utmost care of the tissues so that they may retain their powers of resistance as fully as possible With this must be remembered accurate hæmostasis and temporary drainage of the wound whenever the subsequent formation of a hæmatoma is at all possible
2 By avoiding infection from the patient's own skin, from the hands of the surgeon and his assistants, from instruments, gloves, gowns, mackintoshes, swabs, sutures, and fluids, from the air and through soaked dressings or plaster of paris

CARE OF THE TISSUES

The care of the tissues is of primary importance, for healthy vascular tissues are not easily infected, and their resistance to infection is favoured by good circulation and physical rest On the other hand, they are in danger if they have been bruised or dried by long exposure at operation, especially if they are subsequently devascularised from compression or disturbed by repeated movement

Unnecessary bruising can be avoided by thoughtful and sensitive technique Skill and delicacy of touch, clean sharp dissection without a single avoidable movement, swabbing by momentary pressure without a rub, exposure by design of incision rather than by powerful retraction, all these, with accurate hæmostasis, contribute to the safety and comfort of a wound It is better to operate without a tourniquet when the operation can be carried out with equal accuracy, and when a tourniquet is used it should with few exceptions be removed for hæmostasis before the wound is closed, for long continued compression is an undesirable and often ineffectual means of controlling subsequent bleeding, and a hæmatoma favours suppuration

Every stitch should be tied gently Deep skin stitches which include underlying tissues should not be tied tight enough to bring the skin together, the exact approximation of the skin is better achieved by the way the superficial stitches are inserted than by pulling them tight Finally, in applying a bandage or plaster of paris over the dressings great care should be given to the avoidance of undue compression. Provision should always be made for subsequent swelling, and exact instructions given about the signs and symptoms of compression and the prompt action that should be taken for its relief. Postoperative plasters are better split vertically from top to bottom, and then held by a few bow ties of bandage, which can easily be untied and retied after the plaster case has been adjusted to give complete relief to the patient and to restore free circulation to the part

THE PATIENT'S SKIN

About a third of the population of this country carry *Staphylococcus aureus* in nose or skin, and the proportion is probably considerably higher in hospital staff (Vollum 1950) By no method of preparation has it proved possible to achieve sterility right through the skin, but tests have shown that the painting of dry skin with various liquids, of which iodine 2% in 70% alcohol seems the most effective (Gardner and Seddon 1946), produces a surface which is sterile and will remain sterile for an hour or more unless the sweat glands become active Up to now it has been thought right to prepare the skin the day before operation The area of operation, together with a large margin of safety, after being thoroughly washed and dried, is painted with the antiseptic of choice and wrapped and bandaged in a light sterile towel (heavy coverings are to be avoided lest they promote perspiration) In the theatre the coverings are carefully removed in such a way as to leave the prepared area of skin untouched But the surface is no longer aseptic and must be repainted Professor Gardner, however, writes regarding the use of 2% iodine in 70% spirit "It seems that for surgical incisions also a single painting just before the operation is all that is necessary, and that elaborate washings and other preparation of the skin could be omitted, for we know that no amount of washing removes all the 'resident' bacteria"

---

* Mr Girdlestone died on Dec. 30 1950

[1] In an address (unpublished) to the Association of Surgeons in 1949 Sir Hugh Cairns gave some personal experiences of operative infection "In the first period (1927–38), when I was operating in two nursing homes as well as at a hospital where the theatre opened off the main corridor, the incidence of fatal infection in operations for brain tumour was 2 7% In the second period (1938–44), when I worked in one air-conditioned theatre, the incidence of fatal infection was 1%, and the over all incidence of operative infection, including superficial wound infection and mild meningeal reactions, was 4 4% In 1944, conditions otherwise being unchanged, we began insufflating penicillin sulphamethazine powder into all clean wounds as a routine prophylactic measure, and in the third period (1944–47) the incidence of operative infection fell from 4 4% to under 1% That there were no deaths from infection in this period cannot be attributed solely to prophylaxis, because when infections arose they were energetically treated with antibiotics "

In my own view the part should be thoroughly washed and inspected on the previous day, then left uncovered The skin is less likely to sweat, and the patient is more comfortable during the night without extensive coverings to disturb his sleep and remind him of the morrow In any case it would seem wise for the surgeon to cleanse the skin over the area of the incision with several "ether-meth" swabs before painting it with iodine in spirit

When, however, the incision is made, sweat glands and hair follicles are laid open, and at once the edges of the cut become a possible source of infection

As part of an investigation made at the Wingfield-Morris Orthopædic Hospital (O'Brien 1947) swabs were taken from the cut edges of the skin immediately after incision These grew normal skin flora in about a third of the cases, and further swabbing at the end of the operation revealed a higher proportion of positives From one of two heavy skin carriers of *Staph aureus* identified before operation the organism recovered from the cut edge was of the same phage type (healing was uneventful)

No good purpose is served by pasting fabric on the skin with mastic before making an incision This is one more rite, the mastic is one more material to sterilise and keep sterile, and the appearance of safety is an illusion, for the cut edges of the skin remain exposed

Skin Towels

How best can the wound be protected from infection from the skin? Experience of nearly forty years' operating since I adopted the iodine spirit preparation leaves me doubtful whether the covering of the cut edges of the skin and the skin surrounding the area of operation by skin towels is beneficial, neutral, or harmful. My operating experience can be divided into three parts—about twenty years before I clipped skin towels round the wound, followed by about twelve years of the routine use of skin edge towels for all large or long operations, and, finally, a period in which I have abandoned them (except for operations through windows in plaster of paris) During the towelled skin edge period suppuration developed several times after operations which I had previously done with complete impunity For this experience other factors may be responsible Indeed the period includes the worst war years, when patients' skins were dirtier, and when hospital staff were experiencing repeated nasal contamination from the dressing of heavily infected gunshot wounds (for however effective good masks may be in preventing infection of the air *from* nose and mouth they have little value in the other direction, from air to nose)

Nevertheless it is perhaps worth while to consider the state of affairs round the wound with its edges towelled and not towelled The towels are commonly fastened round the edge with some form of clamp or Michel clip with claws that grip or penetrate the skin These clamps are left in place throughout the operation, however long, they lead to local trauma and ischæmia of the skin, and tend to squeeze out material from the glands The exudation mixes with blood and soaks through the towel along the edge of the wound There must be some danger of staphyloccal infection in both cases, but there is this difference in the towelled wound the margins look safe, whereas in the untowelled wound they look dangerous Therefore the surgeon is ready to allow suture materials, swabs, and so on to brush against the towelled skin edge but is careful to avoid anything of the kind with the uncovered skin edge

The skin towels also cover the surface of skin round the wound But adequate preparation keeps the surface of the skin safe until there is gradual reinfection from its depths Furthermore the surface and edges can be gently wiped after the incision, and every 30 minutes thereafter, with swabs soaked in acriflavine 1/1000 in water, 1% tetrachlorxylol in 70% spirit, or some other relatively non toxic antiseptic If iodine in spirit has been repeatedly applied to the surface of the skin, it is well to wipe the skin well with 70% spirit after closure of the wound

In the hope of getting some further information by experiment on this point, an investigation was undertaken at the Wingfield Morris Orthopædic Hospital in 1949–50 Unfortunately this not only entailed repeated disturbance of major operations but also threw a good deal of extra strain on an overworked laboratory Therefore it was not considered justifiable to continue it very long, and the numbers are relatively small The investigation was made at my request by Mr G Mitchell, the resident surgical officer, who was solely responsible for an investigation covering 98 cases From these he selected a series of 50 comparable operations, 25 with towels and 25 without The remaining 48 operations did not satisfy the criteria as regards severity and length, which were (1) a major operation requiring protracted retraction, and (2) exposure of the wound for over 40 minutes

Material for culture was obtained as follows

No skin towels used—By rubbing the cut edges of the skin (1) immediately after incision, (2) after 30 minutes, and (3) after 60 minutes

Skin towels used—(1) By rubbing the newly cut skin edges before the application of towels, (2) from the surface of the towels where they covered the skin edges 10 minutes after skin towels had been applied, (3) after 30 minutes, and (4) after 60 minutes

When no towels were used, *Staph aureus* was recovered from swabs at both 30 minutes and 60 minutes after the incision in one case and at 60 minutes only in a second case When towels were used, *Staph. aureus* was recovered immediately after incision in one case, and the later swabs over the towels were all negative

To discover whether there was any relation between these findings and postoperative wound sepsis the results of culture and the evolution of the wound in the whole 98 cases were investigated There were 5 patients with positive skin swabs, and of these 1 had an infected hæmatoma, and 1 a superficial stitch infection Of the 93 with negative swabs 1 had an infected hæmatoma, and 2 had a superficial stitch infection

There is a great difference between the finding of "normal skin flora" in rather more than a third of the swabs rubbed along the edges of the incision by Dr O'Brien, and of *Staph aureus* in particular in only 5 out of 98 cases by Mr Mitchell in the later series

It is clear that the number of cases is not sufficient to allow of any conclusion as to the relative advantages of towelling the edges and of leaving them exposed Furthermore, in the investigation any antiseptic wiping of the surfaces and edges of the skin was avoided, so as to favour the collection and culture of bacteria, whereas in my practice this is a periodic precaution

Further bacteriological investigations were made by O'Brien (1947) to discover (1) how far one strain, or a few strains, of staphylococci were responsible for the infection of the 19 cases of surgical infection which were under review , and (2) whether the strain in the pus was the same as that of any *Staph. aureus* recovered from the patient's skin

The organism was a coagulase-positive *Staph. aureus* in 18 cases and *Pseudomonas pyocyanea* in 1 Of the cultures of *Staph aureus*, 16 were sent to Dr V D Allison, who phage typed 12, reporting the other 4 as untypable The strains from 3 patients operated on within six weeks of each other showed the same type, but for the others at least 10 different strains were responsible

The skin of 12 of the infected patients was swabbed some time after infection had become obvious (hence there was the possibility of infection from the wound) In 6 cases skin and nasal swabs did not grow *Staph aureus* , in 1 case the phage type of a staphylococcus recovered from the skin was different from that in the wound, and in 5 the phage type was identical

This evidence supports but does not prove the suggestion that some patients become infected by the staphylococci on their own skin

It is also clear from an investigation carried out by McFarlan (see below) into one case and those of O'Brien (1947) that it is by no means easy to be sure of the source of an infection leading to suppuration Indeed it is noteworthy that, in a case in which a surgeon carrying *Staph aureus* had a punctured glove, the *Staph aureus* recovered from the pus was not of the same phage type as that of the surgeon's hand , in another case, where *Staph aureus* was found on the patient's skin, the suppuration was due to *Staph aureus* of another type , and in a third case, where a heavy carrier of *Staph aureus* (nose and skin) took part in the operation, a similar difference was found. These results make the investigation appear inconclusive , but at the same time they indicate the multiplicity of sources of infection, and suggest that staphylococci of several different groups—e g , from a nurse's nose, a surgeon's hands, or the patient's skin—may simultaneously infect our wounds, and that suppuration may develop only when a cluster of staphylococci (of whatever group) reaches favourable soil ,, bruised devascularised tissue or a hæmatoma

Deep infection seems to be closely related to the length of incision, and the duration of exposure of the deep tissues, for the operations in which such infection has taken place have been operations with long incisions and long exposure, particularly operations on the hip with a Smith Petersen incision, and not operations with relatively short incisions on knee, hand, or foot

Now this is the more remarkable when one remembers that in the big hip operations everything can be done gently and there is very little bruising of the tissues, whereas at the other end of the scale, in subcutaneous tenotomy followed by manipulation, considerable bruising and stretching of structures is entailed and yet infection is almost unknown I have never seen an infected subcutaneous tenotomy though I have done very many, and McCrae Aitken (1935) quotes Robert Jones as saying that his uncle, H O Thomas (in practice between 1859 and 1891), and he had done over two thousand subcutaneous tenotomies without any case of inflammation

Lymphatic Infection

The possibility of the area of operation being infected during or after the operation from a peripheral skin lesion via the lymphatics passing through it must always be remembered for this reason the hand or foot distal to the site of operation on a limb should be carefully examined on the patient's admission.

THE SURGEON'S HANDS

One can do something to avoid becoming a carrier of pyogenic organisms by using instruments for septic dressings, and gloves for palpation near purulent discharge The hands of surgeons and nurses, gloved or not, which have been contaminated by pus, should never be used for turning on a tap or handing a towel. And experiments have shown that it is best to wash with plenty of soap and friction, and with few rather than frequent douches under running water [2]

Living organisms can be left on the surface of the gloves by defective sterilisation, and can be placed there by faulty technique in gloving, but are very much more often transferred from within through a puncture or a tear Infection from within the gloves may be due to incomplete sterilisation of their inner surface, inadequate washing of the hands or their deep infection, or to the escape of talcum powder, which may itself be infected (see below) or add to the danger of the establishment of infection by its foreign body effect

The drying, powdering, and gloving of the hands need considerable care to avoid any risk of contamination,[2] but danger is not over when the gloves are on Care will keep their outer surface as safe as the swabs and instruments *except for the risk of puncture* That this risk is by no means negligible is shown by a recent investigation

Of gloves used in major orthopædic operations in the Wingfield-Morris Orthopædic Hospital in 1947 a puncture or a tear was discovered in 202 out of 816 (24 7%) This figure is remarkably similar to that reported by Devenish and Miles (1939) in their comparable series, in which 1593 out of 6585 (24 2%) were punctured

These figures suggest a very frequent danger of infection from the surgeon's hands The matter was followed up as follows

On 36 occasions, after the surgeon had finished operating, his gloves and those of all assistants were turned inside out and inflated, and three of the fingers were extensively rubbed on blood-agar plates Three of the surgeons and one nurse were found regularly to have *Staph aureus* on the inside of their gloves

All the surgeons and the theatre staff who assisted at operations were frequently tested by nasal swabs and a moistened swab rubbed on the back of each hand and, for a time, throat swabs also These were cultured on blood-agar and Chapman plates, and later the swabs were also immersed in broth and incubated and then subinoculated on to blood-agar plates. *Staph aureus* was isolated regularly from five of the sixteen surgeons and nurses, and occasionally from a further six

The phage type of the organisms recovered from the regular carriers was determined, and the findings compared with the analysis of the twelve strains recovered from the infected patients It is remarkable that in this group, covering the only patients (18) to which this test could be applied, in no instance were the staphylococci grown from the pus of a patient of the same phage type as those grown from the hands of the surgeon who had operated or his assistants

The numbers are small, and suppuration of surgical wounds may well be at present more often due to infection from the surface of the hands through punctured gloves than to any other cause, and it seems well worth while that frequent periodic investigations should be made in all hospitals on the lines of those described by Devenish and Miles (1939)

It is possible for the surgeon to develop a standard of discipline of himself and his team which will ensure that is probably considerably higher in hospital staff (Vollum 1950) By no method of preparation has it proved possible to achieve sterility right through the skin, but tests have shown that the painting of dry skin with various liquids, of which iodine 2% in 70% alcohol seems the most effective (Gardner and Seddon 1946), produces a surface which is sterile and will remain sterile for an hour or more unless the sweat glands become active Up to now it has been thought right to prepare the skin the day before operation The area of operation, together with a large margin of safety, after being thoroughly washed and dried, is painted with the antiseptic of choice and wrapped and bandaged in a light sterile towel (heavy coverings are to be avoided lest they promote perspiration) In the theatre the coverings are carefully removed in such a way as to leave the prepared area of skin untouched But the surface is no longer aseptic and must be repainted Professor Gardner, however, writes regarding the use of 2% iodine in 70% spirit "It seems that for surgical incisions also a single painting just before the operation is all that is necessary, and that elaborate washings and other preparation of the skin could be omitted, for we know that no amount of washing removes all the 'resident' bacteria"

---

[2] The details and order of these processes differ widely in different places , perhaps some standardisation of washing, masking, gowning and gloving is desirable

In my own view the part should be thoroughly washed and inspected on the previous day, then left uncovered The skin is less likely to sweat, and the patient is more comfortable during the night without extensive coverings to disturb his sleep and remind him of the morrow In any case it would seem wise for the surgeon to cleanse the skin over the area of the incision with several "ether-meth" swabs before painting it with iodine in spirit

When, however, the incision is made, sweat glands and hair follicles are laid open, and at once the edges of the cut become a possible source of infection

As part of an investigation made at the Wingfield-Morris Orthopædic Hospital (O'Brien 1947) swabs were taken from the cut edges of the skin immediately after incision These grew normal skin flora in about a third of the cases, and further swabbing at the end of the operation revealed a higher proportion of positives From one of two heavy skin carriers of *Staph aureus* identified before operation the organism recovered from the cut edge was of the same phage type (healing was uneventful)

No good purpose is served by pasting fabric on the skin with mastic before making an incision This is one more rite, the mastic is one more material to sterilise and keep sterile, and the appearance of safety is an illusion, for the cut edges of the skin remain exposed

Skin Towels

How best can the wound be protected from infection from the skin? Experience of nearly forty years' operating since I adopted the iodine spirit preparation leaves me doubtful whether the covering of the cut edges of the skin and the skin surrounding the area of operation by skin towels is beneficial, neutral, or harmful My operating experience can be divided into three parts—about twenty years before I clipped skin towels round the wound, followed by about twelve years of the routine use of skin edge towels for all large or long operations, and, finally, a period in which I have abandoned them (except for operations through windows in plaster of paris) During the towelled skin edge period suppuration developed several times after operations which I had previously done with complete impunity For this experience other factors may be responsible Indeed the period includes the worst war years, when patients' skins were dirtier, and when hospital staff were experiencing repeated nasal contamination from the dressing of heavily infected gunshot wounds (for however effective good masks may be in preventing infection of the air *from* nose and mouth they have little value in the other direction, from air to nose)

Nevertheless it is perhaps worth while to consider the state of affairs round the wound with its edges towelled and not towelled The towels are commonly fastened round the edge with some form of clamp or Michel clip with claws that grip or penetrate the skin These clamps are left in place throughout the operation, however long, they lead to local trauma and ischæmia of the skin, and tend to squeeze out material from the glands The exudation mixes with blood and soaks through the towel along the edge of the wound There must be some danger of staphyloccal infection in both cases, but there is this difference in the towelled wound the margins look safe, whereas in the untowelled wound they look dangerous Therefore the surgeon is ready to allow suture materials, swabs, and so on to brush against the towelled skin edge but is careful to avoid anything of the kind with the uncovered skin edge

The skin towels also cover the surface of skin round the wound But adequate preparation keeps the surface of the skin safe until there is gradual reinfection from its depths Furthermore the surface and edges can be gently wiped after the incision, and every 30 minutes thereafter, with swabs soaked in acriflavine 1/1000 in water, 1% tetrachlorxylol in 70% spirit, or some other relatively non toxic antiseptic If iodine in spirit has been repeatedly applied to the surface of the skin, it is well to wipe the skin well with 70% spirit after closure of the wound

In the hope of getting some further information by experiment on this point, an investigation was undertaken at the Wingfield Morris Orthopædic Hospital in 1949–50 Unfortunately this not only entailed repeated disturbance of major operations but also threw a good deal of extra strain on an overworked laboratory Therefore it was not considered justifiable to continue it very long, and the numbers are relatively small The investigation was made at my request by Mr G Mitchell, the resident surgical officer, who was solely responsible for an investigation covering 98 cases From these he selected a series of 50 comparable operations, 25 with towels and 25 without The remaining 48 operations did not satisfy the criteria as regards severity and length, which were (1) a major operation requiring protracted retraction, and (2) exposure of the wound for over 40 minutes

Material for culture was obtained as follows

No skin towels used—By rubbing the cut edges of the skin (1) immediately after incision, (2) after 30 minutes, and (3) after 60 minutes

Skin towels used—(1) By rubbing the newly cut skin edges before the application of towels, (2) from the surface of the towels where they covered the skin edges 10 minutes after skin towels had been applied, (3) after 30 minutes, and (4) after 60 minutes

When no towels were used, *Staph aureus* was recovered from swabs at both 30 minutes and 60 minutes after the incision in one case and at 60 minutes only in a second case When towels were used, *Staph aureus* was recovered immediately after incision in one case, and the later swabs over the towels were all negative

To discover whether there was any relation between these findings and postoperative wound sepsis the results of culture and the evolution of the wound in the whole 98 cases were investigated There were 5 patients with positive skin swabs, and of these 1 had an infected hæmatoma, and 1 a superficial stitch infection Of the 93 with negative swabs 1 had an infected hæmatoma, and 2 had a superficial stitch infection

There is a great difference between the finding of "normal skin flora" in rather more than a third of the swabs rubbed along the edges of the incision by Dr O'Brien, and of *Staph aureus* in particular in only 5 out of 98 cases by Mr Mitchell in the later series

It is clear that the number of cases is not sufficient to allow of any conclusion as to the relative advantages of

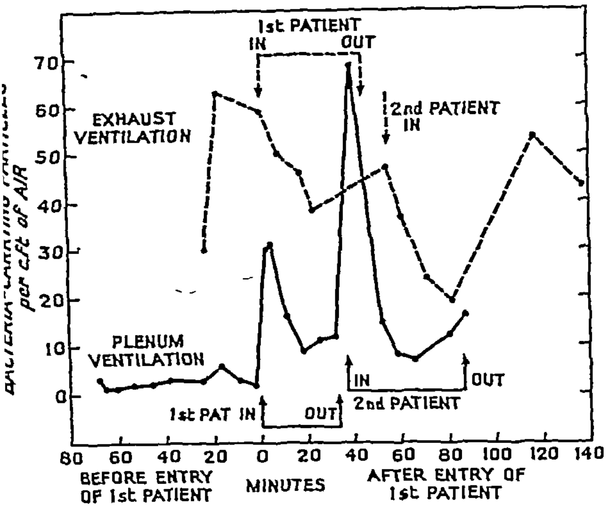

Fig. 1—Airborne bacteria in Wingfield Morris theatre.

This process is illustrated by the series of tests shown in figs 1–3. Fig 1 gives the total counts of bacteria-carrying particles per c. ft. of air found with a slit sampler (Bourdillon et al. 1948) in the Wingfield orthopædic theatre before and during operations. The sampler was placed about 2 ft. 6 in. from the patient's head in the position shown at S_1 in fig 2. The interrupted line shows the counts obtained during part of a typical session of operations with exhaust ventilation only. After starting at 30 infected particles per c. ft. of air the count rose to 63 about a quarter of an hour before the entry of the first patient. It then fell slowly, and showed irregular variations for the rest of the morning. For most of the time it remained at over 30 per c. ft., and only fell below 20 for a brief period.

The cause of the strikingly high figures found before the entry of the first patient was then studied as follows. It was evident that these figures might be due either to very fine particles that had remained suspended for a long time, or to some special source of infection arising in the preoperative period. Samples taken at intervals during the night and the early morning showed counts of only 2 or 3 per c. ft., thus proving that the trouble was not due to the long-continued suspension of very fine particles. It was also found that switching on the exhaust fan and sweeping the floors of the theatre and corridor during the night caused only a moderate rise in the contamination of the theatre air (to about 25 per c. ft.), in contrast to the higher figures shown in the preoperative periods. A detailed study was therefore made of the events occurring before a morning's session of operating. Three observers, each using a slit sampler, recorded the bacterial air counts and the movements of personnel, blankets, &c., in the theatre, corridor, and anæsthetic room from 6.45 to 9.20 A.M. A plan of the theatre and adjacent rooms, &c., with the position of the samplers, is shown in fig 2. The theatre sampler was always used in about the same position in relation to the operating-table.

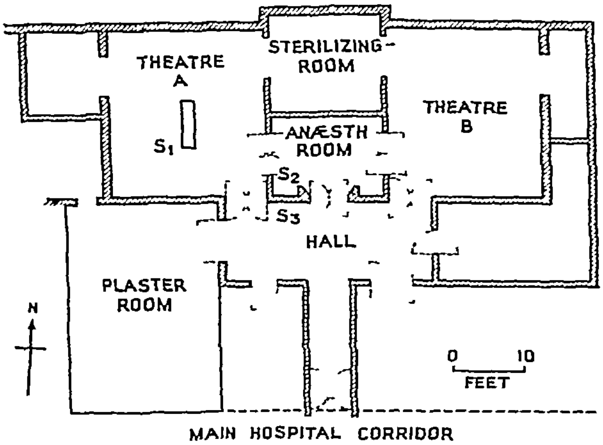

Fig 2—Plan of theatre showing positions of samplers S_1, S_2 and S_3.

This study showed that a rise in bacterial counts in all three samplers began as the first patients entered the hall outside the theatre, and increased rapidly when the ward blankets were changed for the theatre coverings before the patient entered the anæsthetic room. The greatest rises took place just after the change of the second patient's blankets. The order in which the highest counts were reached at the three sampling points was the same as would be expected from the direction of the air flow as shown by smoke tests. Thus air flowed from the hall both directly under the theatre doors and through the anæsthetic room into the theatre (also under the doors). The maximal counts appeared first in the hall, next in the anæsthetic room, and last in the theatre. These results seemed conclusive evidence that the chief cause of high contamination of the theatre air during the preoperative period was the sucking-under the doors of air from the hall and anæsthetic room floors, contaminated by dust from the ward blankets, the porters' feet, and so on.

The further question was considered how far the theatre air might be infected by air from the plaster room, which opened on to one side of the hall, and in which infected wounds were often handled at that period. The results of tests on this point are shown in fig 3. This gives the counts obtained in two tests taken at night, with the rooms empty except for the experimenters. In each test the theatre air was sampled for bacteria with the exhaust fan running and all doors closed, and half way through the test the air in the plaster room was contaminated by sweeping the floor. Test *a* was done in a light north easterly breeze, and test *b* in a south west wind. The difference is striking, and shows the importance, in studies of this type, of taking observations in at least two different states of wind and weather, instead of relying on a single day's tests.

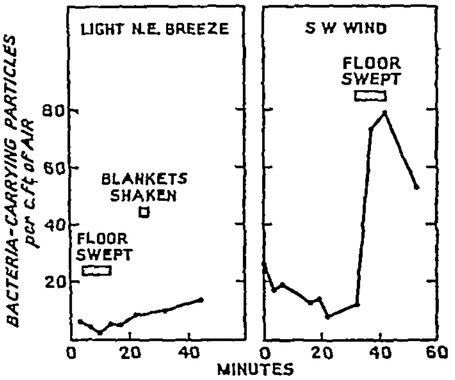

Fig 3—Effect of stirring up dust in plaster room with all doors shut on bacterial count in theatre air.

It was thus clear that the exhaust fan in the theatre unit caused the introduction of large quantities of dirty dust laden air, which might at any moment be dangerous if it included active pathogens. The hospital authorities decided promptly that conditions must be improved, in spite of war time shortages, and a 'Plenum' (positive pressure) system of ventilation was installed. In this plant a 2 h.p. motor in the basement drew clean air from above the roof of the hospital and forced it through oiled metal filters to remove insects and coarse particles, and then into the theatre through two openings (each 42 × 15 in.) controlled by adjustable louvres above the theatre doors. The old exhaust fan above the sterilisers was retained, but, since it was of much lower output than the input no swab, needle, ligature, or part of an instrument which has been touched by the gloved hand enters the wound. But for some operations and some operators the gain in touch, delicacy, and speed justify the direct use of gloved hands (except by carriers of staphylococci or streptococci).

INSTRUMENTS, EQUIPMENT, AND MATERIALS

The procedure described below is based on accepted practice which has been modified in certain directions in the Wingfield Morris Orthopædic Hospital as a result of tests of sterility. It is essential to test periodically the efficacy of drum sterilisation of various awkward articles such as mackintoshes and bandages.

Drum Sterilisation

To ensure the sterilisation of the inner surface of *rubber gloves* it is necessary to facilitate the entry of steam. The following procedure has proved effective:

The rubber gloves are packed loosely with the wrist reflected and the palm held open with a pad of gamgee tissue. Each pair of gloves is put in a loose double folder of lint; in one of the pockets of this folder is placed a very small quantity of talcum powder in a flat muslin packet. To ensure the sterilisation of the talcum powder the additional precaution has been taken of previously exposing it in thin layers (less than $^1/_4$ in. deep) on flat trays for two hours to a temperature of 160–180°C. For the gloves 5–10 lb. pressure for 20 minutes is adequate.

Gowns, towels, mackintoshes,[3] *&c.,* are sterilised at 20 lb. for 30 minutes, or 15 lb. for 45 minutes.

Sterilisation tests are carried out every three weeks in the following manner:

Living spores of an unnamed aerobic bacillus isolated from the soil, relatively heat-resistant and proved satisfactory for the purpose, are obtained from the bacteriological laboratory on a piece of string in a screw-top bottle. The screw is loosened and the bottle placed in the centre of the drum, or the place least accessible to the steam. This method of testing is applied to all drums whatever their contents.

Instruments, and Suture and Ligature Materials

Ordinary instruments are boiled in 1% sodium bicarbonate for five minutes. *Knives* are boiled for three minutes, and then kept in 90% spirit. *Chisels* and *nibblers* are sterilised in oil at 250°F (121°C) for 10 minutes. *Needles* are kept in equal parts of lysol and 70% methylated spirit. After dirty cases the needles are boiled in 1% sodium bicarbonate for 10 minutes, and then kept in the lysol spirit solution. After clean cases the needles are put into pure lysol for half an hour, and then kept in the lysol spirit solution.

Suture and ligature materials have been subjected to much study. They fall into two classes: (1) those that can be sterilised by boiling but remain undissolved in the body, constituting a potential source of trouble if infection arises; and (2) catgut, desirable for its solubility within the body but requiring a high standard of sterilisation by its "manufacturers." Further, the handling of these materials within the theatre, whether on reels or in sealed tubes, calls for a safe ritual. *Silk* and *linen thread* are steam sterilised at 10 lb. for 30 minutes, wound rather loosely and in fairly short lengths on glass reels; after use the reels are boiled for 3 minutes in 1% sodium bicarbonate, then kept in 1–60 phenol. *Silkworm gut* and '*Nylon*' are boiled for 10 minutes, and after use the hanks are boiled again for 3 minutes, then stored in 1–60 phenol. The sterile tubes of *catgut* are kept *under* 1–60 phenol until they are taken out for use.

Beef bone pegs are boiled for 15 minutes, then stored in equal parts of 'Dettol' and 70% spirit.

Specimens from all these materials are examined for sterility every six months.

Bandages

Wool bandages for use under plaster are unrolled and rolled again loosely before sterilisation, to avoid the risk of their proving impermeable to the steam. All felt, gamgee, lint, wool, &c., used in the theatre is sterilised before it is brought in.

Wherever *plaster of paris* is applied over the wound it is first covered with several layers of sterile gauze and plaster wool. It is possible for pathogenic organisms in the plaster to be carried through the sterile dressings during the application of the plaster, or to infiltrate a subsequent exudation of bloody fluid from the wound.

Twenty-seven plaster bandages taken from stock at different times grew no organisms of the species commonly recognised as pathogenic. The home-made plaster bandages occasionally grew *Staph. albus*; hence presumably they could be infected during manufacture by a heavy *Staph. aureus* carrier.

The felt used under plaster is autoclaved against spore-bearing organisms before it is brought into theatre or plaster room.

THE OPERATING THEATRE

Where the theatres are large there is little danger of direct contamination of the walls. At the Wingfield these are washed down with a weak solution of dettol in water once a week. The floors are swabbed and squeegeed with 2% lysol at the end of the day's operating, using a stirrup pump spray, and are subsequently washed with ordinary soap and water. Overhead lamps are wiped and oiled every day to avoid the risk of falling particles. Tables and anæsthetic machines are washed with 2% dettol. If the portable X-ray machine is taken into the theatre it is wiped over, including the wheels, with 2% dettol, and the machine and cassettes are draped with sterile towels.

II.—Airborne Infection

(R. B. B.)

There should be little need to justify the desirability of avoiding airborne infection as far as is practicable. That air contamination in theatres is a real danger is suggested by personal experiences published by Cairns (1939), Robinson et al. (1946), and Sevitt (1949) in this country and by the studies of Hart (1938) and others in the U.S.A.

It is true that in many theatres the dangers of contact infection are probably greater than those of airborne infection, but this does not afford proper grounds for neglecting simple measures such as improved ventilation, which will often do much to reduce air contamination.

The chief sources of air contamination are the air-supply to the theatre and infection of the air in the theatre by the surgeon and his staff and by the patient and his coverings.

AIR-SUPPLY TO THEATRE

It is a remarkable fact that it has been the usual practice in this country to ventilate theatres solely by exhaust fans, without any serious consideration of the routes by which the air enters the theatres. These exhaust fans are installed with the primary purpose of removing steam from sterilisers. Though they do this efficiently, they often have the serious drawback of sucking air and dust at high velocity under the theatre doors. Even when special inlets are provided for the air, these often, if fitted with a filter, have sufficient resistance to air flow to cause an appreciable reduction of air-pressure in the theatre, and, not infrequently, are blocked up altogether to avoid draughts. As a result of this reduced pressure, if the air in the corridor outside the theatre is contaminated with dust (from ward blankets or other source), large numbers of bacteria will be sucked in under the doors and distributed throughout the theatre air.

---

[3] For the importance of adequate cleansing of mackintosh aprons see Corry (1950).

standards for theatre air have been suggested recently by Bourdillon and Colebrook (1946) For the total number of airborne particles carrying organisms which grow to visible colonies after twenty four hours on blood-agar at 37°C, after sampling during periods of quiet operation, the figures suggested were as follows (1) for rooms used for dressing small wounds or for minor operations only, 20 per c ft , (2) for theatres used for ordinary major operations, 10 per c ft , and (3) for theatres used for long operations on easily infected tissues, 2 0–0 1 per c ft The lower counts can only be maintained by taking pains and spending money on ventilation plant

We wish to thank Prof A D Gardner, Dr A T Robb Smith, Mr R L Vollum, D.PHIL., Dr A. M McFarlan, Dr J R O'Brien, Dr J. Cairns, and Dr M Pickles for assistance in the bacteriology , surgical colleagues for their coöperation, and Dr McFarlan for taking and studying samples of airborne bacteria

Appendix

INVESTIGATION OF WOUND INFECTION

(A. M McF)

On Jan 26, 1942, a request was made for investigation of a case of wound infection following operation A visit was paid to the hospital, and it was learnt that the patient, a woman aged 44, admitted on Jan 19, 1942, had undergone next day a subtaloid arthrodesis and had a plaster case applied On the evening of Jan 23 the patient's temperature rose to 104 2°F On Jan 24, a window was cut in the plaster and the dressing was inspected , it appeared clean and was not disturbed On Jan 25, the dressing was foul smelling It was removed, and a fresh plaster was applied The patient's temperature was swinging between 101° and 104°F On Jan 26, sulphapyridine was given by mouth 2 g initially and 1 g four-hourly thereafter On Jan 27, the wound was dressed with soft-paraffin gauze On Jan 29, eusol dressings were applied, and the plaster was changed The wound subsequently improved satisfactorily

Cultures of swabs taken from the wound on Jan 25, yielded *Strep pyogenes* group A, type 27 , *Staph. aureus* coagulase positive , *Bacillus mesentericus*, and *Bact aerogenes*

Cultures of swabs taken on Jan. 27, yielded *Strep pyogenes* group A, type 27 , *Staph aureus* coagulase-positive , and *Bact aerogenes*

Probably the serious infection of the wound was due to the hæmolytic streptococcus, but the staphylococcus may have played some part The presence of *B mesentericus* and *Bact aerogenes* suggested the possibility of an infection by dust

Possible Sources of Infection

The Patient —Neither the patient nor anyone in the house where she had been living had recently had a respiratory infection. Previous operations on her ankle had not been followed by infection

Those Present at the Operation —Nose and throat swabs were taken of the surgeon who assisted and of the theatre staff, but none was found to be a carrier of hæmolytic streptococci The theatre nurses had all had colds recently but had been wearing thicker masks than usual The nurse who took the operation on Jan 20 went off duty on Jan. 23 with an upper respiratory tract infection. On Jan 26 she was carrying considerable numbers of coagulase-positive *Staph aureus* in her nose Thus no evidence was obtained that there was a carrier of hæmolytic streptococci in the theatre

Several visitors were present at the operation, and there was a considerable amount of coughing Some of the masks provided for visitors were small and thin, and the visitors may have contributed some organisms to the air

Dressings and Plaster —The arrangements for sterilisation in the autoclave were excellent and controlled by Browne tubes The patient operated on before the present patient had plasters applied, and no infection had arisen Two patients had had skin-grafts done later in the morning and had shown no signs of superinfection Thus there was no evidence of a gross failure of sterilisation on the day in question

Possibly, however, the plaster-wool which was put in the autoclave in tight rolls was not always sterilised completely Still more worthy of consideration was the unsterilised plaster-wool, which lay on the plaster-room trolley exposed to the air, and the outer exposed part was applied next to the skin Possibly moisture from the plaster and exudate from the wound might have permeated both unsterile and sterile plaster-wool and the sterile dressings, and organisms present in the unsterile wool thus passed to the wound

Samples of plaster-wool were examined, and *B mesentericus* and *Bact aerogenes* were isolated from an unsterilised roll taken from the theatre store cupboard These strains showed the same morphological, colonial, and biochemical reactions as those isolated from the wound This suggested that organisms might pass to the wound from unsterile plaster-wool. Many of the organisms in cotton-wool may be harmless, but it has been shown that tetanus spores may be present , hence thorough sterilisation is necessary

Air of Theatre and Plaster Room.—During observations on the bacterial content of the air in the theatre and plaster room aerobic spore bearers appeared on the plates, sometimes in considerable numbers, after a patient had been moved in Some strains showed a peculiar spreading growth with greening of the blood-agar plate A similar growth was obtained when cultures were made of a roll of plaster-wool taken from the plaster-room trolley This is evidence that organisms present in the air settle on the materials exposed on a plaster trolley Coagulase-positive staphylococci and hæmolytic streptococci have been found in the air, but only occasionally and in small numbers Possibly, however, sufficient numbers of a virulent strain to initiate infection might settle on plaster-wool and so gain access to wounds

Summary and Recommendations

After a clean operation a wound became infected with a type-27 hæmolytic streptococcus, a coagulase-positive staphylococcus, *Bact aerogenes*, and *B mesentericus*

No evidence of the source of the streptococcus was obtained

The theatre nurse who took the operation was later found to be carrying a coagulase-positive staphylococcus in her nose This cannot be considered to incriminate her, for no investigation was made of many possible reservoirs of staphylococci in the noses of the visitors and on the skin of those taking part in the operation

Bact aerogenes and *B mesentericus* were isolated from an unsterilised roll of plaster wool. The application of a plaster over unsterilised materials may allow organisms to penetrate the sterile dressings

Plaster-wool exposed on a trolley in the plaster room may be contaminated by organisms present in the air

It is suggested that (1) efficient masks should be provided for all those present at operations , (2) all plaster wool used under a plaster should be autoclaved, and before autoclaving the rolls should be unwound and rolled loosely to ensure their penetration by steam , and (3) plaster-wool should not be exposed on the plaster-room trolleys either before or after sterilisation

Vollum R. L (1950) Personal communication

fan, the net result was a slight positive pressure in the theatre, so that air always flowed outwards under the doors to the hall and anæsthetic room This system proved most satisfactory The continuous line in fig 1 shows typical bacterial counts obtained during a session of operations with the new ventilation It is noteworthy that, until the arrival of the first patient, all counts were less than 10 per c ft, and that, although much higher counts were produced at the time of the entry and arrangement of each patient at the beginning of an operation, these counts fell rapidly during the quiet operation to a point below 10 per c ft This was in striking contrast to the results obtained previously with the exhaust ventilation, when the continued entry of dirty air from outside had often prevented the counts from falling below 20–30 per c ft (cf the interrupted line in fig 1)

In addition to its effect on airborne bacteria, the new ventilation system gave increased comfort to the surgeons and nurses This was obtained by directing the adjustable louvres through which the air entered the theatre so that a gentle stream of air flowed towards the heads of the staff without causing any appreciable draught at the level of the patient Though thermostatic control of the steam grille would have given a more uniform temperature, manual control was much cheaper, and proved satisfactory under the control of a capable theatre sister The input fan was designed to deliver up to 3000 c ft per min into the total theatre volume of about 15,000 c ft—i e, to give about twelve air changes an hour With the inlets provided, this was found slightly draughty, and the fan speed was adjusted to give a rather lower figure With more inlets the larger flow would have been preferable

Effect of Temperature on Inflow of Corridor Air

It is worth remembering that, although a good plenum system will cause a uniform outflow of air from a theatre while the doors are shut, it cannot prevent some entry of air from the corridor when the doors are open, since the mean pressures in the two spaces become practically equal almost immediately after the door has been opened The amount of air then entering depends chiefly on the temperature differences between theatre and corridor If the corridor air is much cooler than the theatre air, a brisk exchange will begin, the cool corridor air flowing into the theatre through the lower half of the door and displacing warmer theatre air through the upper half. This is easily demonstrated by a smoke test—e g, by holding a cigarette at different heights near the edge of the door If the air temperatures in theatre and corridor are nearly equal, little air movement will take place

Though such air exchange is undesirable, and indicates a need for keeping the corridor air tolerably clean, it is much less dangerous than the sucking of air under the theatre door, since the thermal air currents move relatively slowly and do not pick up bacterial particles from the floor

INFECTION OF AIR IN THEATRE BY SURGEONS AND NURSES

Infection from the respiratory tracts of the staff should always be regarded as a potential danger, even when the utmost care is taken with masks I have not yet seen a mask capable of retaining all the infectious particles emitted during a vigorous sneeze, and tests made with a slit sampler during a quiet operation in the presence of an assistant surgeon with a cold have shown a sudden emergence of α hæmolytic organisms into the theatre air just after a coughing fit There can be no doubt that the rigorous exclusion from operating-theatres of all persons carrying an active infection is highly desirable, even though it may be very difficult at times

Infection from particles scattered from the hair of the staff, including their eyebrows and eyelashes, should also be guarded against Though the hair of everyone in the theatre should be fully covered, it is desirable that those taking direct part in the operation, who are liable to place their heads above the wound, should have applied oil or a cosmetic cream to their hair, face, eyebrows, &c Without this precaution slight movements causing friction between the edges of the cap, the tapes of the mask, and so on, may cause a shower of bacteria to fall into the wound This danger is increased if two persons' heads accidentally touch over the wound

The clothing of assistant staff is often a possible source of contamination, especially when gowns left partly open at the back rub to and fro over woollen jerseys It should be a rule that no unsterilised woollen clothes should be visible in the theatre, at least at any level above 1 ft from the floor

INFECTION OF AIR IN THEATRE BY PATIENT AND HIS COVERINGS

The patient's nasopharynx can be an appreciable source of infective particles, especially if he is coughing, or has coughed during the induction of anæsthesia When practicable, it is desirable that the direction of air flow in the theatre should be from wound to anæsthetist rather than the reverse The logical development of such considerations is the use of a duct carrying a stream of sterile air, of controlled temperature and humidity, playing directly on to the wound at a low velocity, and so excluding the possibility of contamination from the surrounding air This is, however, only worth considering when standards of asepsis are already high and specialised operations make the avoidance of airborne infection of especial importance

The patient's skin and coverings are potent sources of bacterial clouds, and it is usual to find when sampling theatre air during operations that the turning over of a heavy patient, or the movements attendant on the arrival of a fresh patient, cause a considerable increase in the number of airborne bacteria (see continuous line in fig 1) It is now recognised that unoiled blankets, sheets, pillow cases, and patients' nightgowns or pyjamas readily liberate bacterial clouds, unless recently sterilised Although ward blankets are now rigorously excluded from most theatres, very questionable things are still done For instance, I have seen a patient walk into the theatre in a woollen dressing gown and even climb on to the table with it, thus liberating thick clouds of bacteria just before the operation Again, although ward blankets are excluded before an operation they are sometimes admitted at the end of it, without regard to the effect on the air for the next patient

A good method of dealing with the problem of bacteria from textiles is to arrange for instruction in the technique of oiling these fabrics to be given to the hospital laundry (Harwood et al 1944), and to have all the patient's coverings oiled, except those which are sterilised immediately before use Tests have shown that the use of a theatre blanket kept solely in the theatre, and always used in a sterilised cotton cover which is renewed each morning, is a reasonably clean procedure There is, however, little doubt that it becomes safer if the blanket is oiled during laundering so as to reduce the number of fine particles shed inside the cover

STANDARDS OF AIR PURITY

It is now common practice to insist on certain standards of purity before water is considered fit for drinking Although similar standards for the purity of air have not yet been widely accepted, it does seem reasonable to suggest that hospitals and surgeons should pay some attention to the cleanliness of the air in operating theatres, and should insist on the attainment of at least a moderate standard of cleanliness Provisional

When the effect of previous relapses on the efficacy of treatment was investigated, no correlation could be made out between them The number of relapses before treatment was begun did not influence the subsequent chances of relapse, whatever treatment was used Some workers have maintained that several relapses before treatment render it more effective, others that the reverse is true Treatment made no difference to the duration of subsequent relapses.

VALUE OF NEOARSPHENAMINE

Opinions on the value of neoarsphenamine in relapsing fever vary remarkably widely There is no doubt that some enthusiastic reports have been misleading, and there is little good evidence in its favour In reports such as those of Wright and Harold (1920), Briggs (1935), Ordman (1939), and Magee (1942), where claims are made for organic arsenicals, numbers of cases are admitted where relapses occurred On the whole, good effects were noted more often in the earlier papers on the subject

Dissatisfaction has been voiced by many workers—e g, Nicolle (1932), Adler et al (1937), Bulmer (1943), Marques (1944), and Quin and Perkins (1946) In fact most workers report poor effects with neoarsphenamine in this form of relapsing fever

This resistance to treatment has been variously explained Increasing resistance to arsenic has been postulated by Hindle (1931), but this seems unlikely to be the explanation in Cyprus, where tick-borne relapsing fever, only recently recognised and never before treated there, was found at once to be relatively refractory to neoarsphenamine

Several factors have probably caused the present uncertainty (1) it is clear that many patients have not been followed up for the necessary month or six weeks after treatment to ensure that relapses were not missed, (2) some workers' criteria of cure seem to include the possibility of relapses, and (3) there is evidence that different strains of spirochætes differ in their susceptibility to the drug

Charters (1942), Magee (1942), and Stuart (1945) favour large doses of neoarsphenamine rather than small ones, especially if given early The present series offers no evidence for or against this method Suggestions that full doses are dangerous in tick-borne relapsing fever are for the most part unconvincing No fears need be entertained, provided the patient is otherwise in good health

In louse borne relapsing fever it has long been held that neoarsphenamine is effective Here also doubts are beginning to arise (Chung and Chang 1939, Wolman 1944) but probably the drug is of greater value in louse borne than in the tick borne form In assessing the results of treatment it must not be forgotten that the former usually causes a much shorter illness

OTHER DRUGS

Most of the other drugs that have been tried are not superior to neoarsphenamine, and many are without any effect (Hindle 1931, 1935) The more recent of them that merit notice are sodium potassium bismuth tartrate (Todd 1930, Kammer 1943), 'Stovarsol' (Van Nitzen 1927, Bulmer 1944, Stuart 1945) tryparsamide (Hawking 1941), oxophenarsine ('Mapharsen') (Stuart 1945), gold compounds (Wolman et al 1945 Dubois 1932), and antibiotics.

Of these, oxophenarsine deserves more extended use

Hopes that penicillin would cure relapsing fever (McAlpine 1946, Lourie and Collier 1943, Heilman and Herrell 1943, Eagle and Magnuson 1944, Augustine et al. 1944, Schuhardt and O'Bryan 1944) are unfortunately not likely to be fulfilled (Tucker 1946, Muwazi 1946, Pospelova-Strom and Tiburskaya 1946, Anderson 1946)

Heilman (1945) who tried the effect of streptomycin in experimental relapsing fever, did not think the results were so good as with penicillin, but Levaditi and Vaisman (1947) thought streptomycin was better, especially at eradicating brain infections in mice infected with *Sp duttoni*

Aureomycin was tested by Heilman (1948), who found it more effective than penicillin at sterilising the bloodstream Its effect on brain infections is not yet known

SUMMARY

The effect of neoarsphenamine in the treatment of 82 cases of tick-borne relapsing fever in Cyprus in 1942–43 has been studied On the whole the response to treatment was unsatisfactory

A course of three or four injections given at intervals of 5–7 days brought the relapse-rate down to 17 4% (23 cases) One injection, usually given during the fever, produced a relapse rate of 53% (34 cases), or, if the 12 cases of Wood and Dixon (1945) are included, of 50% (46 cases) Two injections brought the relapse rate down to 38 5% (13 cases) The advantages of multiple doses are discussed

When multiple intravenous doses of neoarsphenamine are used, the first should be 0 45–0 6 g and subsequent doses 0 6 g given at intervals of not more than seven days No evidence of any toxic effects with this dosage was found among Indians, who formed the majority of the patients

Alternative forms of therapy are briefly described From the work of others penicillin seems to be about as efficacious as organic arsenicals. Other drugs with interesting possibilities are tryparsamide (for neurological complications), oxophenarsine, gold compounds, and several antibiotics, or several remedies can be used together

I wish to thank Majors R C Wood and K C Dixon, R.A.M.C, and Major B J Doran, I.A.M.C, for allowing me to refer to cases under their care and for giving me details of treatment used, Captain B Brown I.A.M.C, for his coöperation and help, and Captain D Pietroni R.A.M.C and Captain S Bose, I.A.M.C, for their help.

TREATMENT OF TICK-BORNE RELAPSING FEVER

NEOARSPHENAMINE AND OTHER REMEDIES

N F Coghill
M A , M B Camb , M R C P ,
PHYSICIAN, WEST MIDDLESEX HOSPITAL , LATE MAJOR R A M C , MEDICAL SPECIALIST

The therapy of tick-borne relapsing fever has always been unsatisfactory No apology is needed for further consideration of neoarsphenamine, for penicillin and the later antibiotics have not proved more effective

MATERIAL

Tick borne relapsing fever occurred among military personnel in Cyprus in 1942–43 (Wood and Dixon 1945, Gambles and Coghill 1948) Records of the treatment of 82 cases are available, including the 12 cases of Wood and Dixon (1945), the 35 reported by Coghill (1949), and 35 from different hospitals on the island Among these 82 there were 7 in which the diagnosis was not confirmed by the finding of spirochætes in the peripheral blood , but clinically they were undoubted cases of relapsing fever

METHOD

The preparations of neoarsphenamine used were ‘Sulphostab’ and ‘Novostab,’ both intravenously Tryparsamide, bismuth, and potassium iodide were used in 1 case with facial palsy

There is a general opinion that neoarsphenamine should be given as the temperature is rising at the beginning of an attack of fever For various reasons it often proved impossible to do this, but most of the patients received their initial injection when febrile Although on theoretical grounds there is not a great deal to favour this practice, it is probably true that in single dose methods of treatment neoarsphenamine is best given early in the febrile phase

After relapsing fever had been dealt with for some months, investigation showed that different methods of treatment were used at different centres in the island Since a single dose of neoarsphenamine often failed to prevent relapses, some medical officers had begun to give two or more injections of the drug in the form of a short course This system of treatment was first suggested to me by Captain B Brown, I A M C , but previous attempts had been made to show that multiple doses of neoarsphenamine are better than single ones (Kassirsky 1933, Ordman and Jones 1940, Stuart 1945) Katz (1930) suggested that the injections need not necessarily be given with strict regard to the stage of the disease

Various considerations finally led us to believe that three doses at intervals of about a week might be the best form of treatment It is commonly supposed that neoarsphenamine acts better on the spirochætes when they are in the blood stream (i e , during fever), but there must always be some remaining in the internal organs These are more likely to be affected by neoarsphenamine given over a period than by one injection, no matter when it is given Unfortunately little is known about the action of neoarsphenamine in relapsing fever Doubts naturally arise as to its efficacy when patients contract relapsing fever after a large dose of neoarsphenamine (Johnson 1925, Magee 1942) or relapse within a few hours of a third or fourth dose (Sergent et al 1933, Coghill 1949)

In the earlier cases the patients tended to receive only one injection of neoarsphenamine, whereas in the later cases they more commonly received two, three, or even four injections as initial treatment The treatments used in the 82 cases were as follows

Treatment	*Organic arsenical*
A	0 45 or 0 6 g , usually during fever
B	0 6 g usually during fever 0 6 g eight days lat
C	0 3 or 0 45 g , usually during fever , 0 45 or 0 6 from five to eight days later
D	0 3 g , usually during fever , 0 45 g five days later 0 6 g seven days later
E	0 6 g usually during fever , 0 6 g seven days late 0 6 g seven days later
F	0 3 g , usually during fever 0 6 g five days later 0 6 g seven days later
G	0 6 g , usually during fever , 0 6 g five or six day later , 0 45 g five or six days later , 0 45 g five or six days later

The chief reason why many patients received low doses, at least at the first injection, was that the medical officers feared toxic effects in Indians, who comprised 63 of the 82 patients It was supposed that they were peculiarly intolerant of arsenic The basis for this belief was not clear, but it might be justified by the fact that many Indian soldiers weighed relatively little (Garland 1946) There was no evidence that any patient sustained hepatic or other damage from the doses of neoarsphenamine used in this series

A single injection of neoarsphenamine was given in 46 cases, and multiple doses in 36

RESULTS

The results of the different treatments are shown in the accompanying table It has been assumed, probably with good reason, that if a patient relapsed at his unit after treatment he was readmitted to one of the hospitals on the island , so the records of all were scrutinised Many of our own cases were retained in hospital for three or four weeks after the last relapse Others were followed in a local convalescent depot It is therefore unlikely that many relapses were missed Since follow up measures were more stringent in the later cases, relapses are most likely to have been missed in the earlier ones, which mostly received treatment A The table shows that multiple doses—those after the first being given without special regard to the clinical state—were better than a single injection given usually during the fever The relapse rate was 50% when only one dose was given (treatment A), came down to 25% when two or more doses were given (treatments B–G), and to 17% when three or more were given (treatments D–G) Although the results with neoarsphenamine were on the whole unsatisfactory, the figures indicate a relative improvement with multiple doses

RESULTS WITH THE DIFFERENT METHODS OF TREATMENT

Treatment	A	B	C	Total of B and C	D	E	F	G	Total of D–G	Total of B–G	Total of A–G
No of patients treated	46 (12)*	1	12	13	14	2	4	3	23	36	82
No of patients who relapsed after treatment	23 (5)*	1	4	5	1	0	3	0	4	9	32
Relapse rate (%)	50			38 5					17 4	25	39

* Figures in parentheses are those of Wood and Dixon (1945) and are included in the totals

In the cases which relapsed the only effect of treatment, apart possibly from the shortening of the attack in which it was given, was to delay the appearance of the next relapse, sometimes considerably The longest interval was 39 days from the end of an attack to the appearance of a relapse Afebrile periods in treated patients were not often so long, and were usually no more than double those of untreated patients This phenomenon has been described before, by Manson and Thornton (1919), Marques (1944), and Wolman (1944) Intervals between attacks in untreated cases in Cyprus were usually 3–6 days and seldom more than 8

Quick and Stefanini (1948a) A modification of this method is described below All these determinations were made with a human brain thromboplastin prepared by dehydration with acetone according to the method of Quick (1945) and capable of clotting an equal volume of oxalated fresh human plasma in twelve seconds in an optimal concentration of $CaCl_2$

Quantitative One-stage Assay of Concentration of Labile Factor in Plasma

The prothrombin time of oxalated human plasma stored at 4°C for about fifteen days is much prolonged owing to the striking and prompt depletion of the labile factor When 1 volume of fresh oxalated human plasma is added to 9 volumes of stored plasma, the prothrombin-time of the mixture is reduced to twenty seconds (Stefanini and Quick 1948) When a given plasma is deficient in labile factor, the prothrombin-time of the mixture is directly proportional to the extent of this deficiency

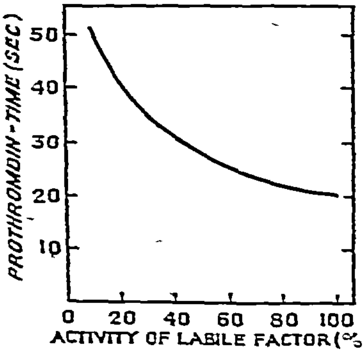

Fig 1—Curve for calculation of activity of labile factor in human plasma from prothrombin-time. Decreasing volumes of fresh normal oxalated plasma were mixed with increasing volumes of saline solution to obtain known concentrations of the labile factor from 100 to 10%. To 0·09 ml. of stored human oxalated plasma 0·01 ml. of each different dilution was added and the prothrombin-time of the mixture was determined. An optimal concentration of prothrombin was present in each mixture.

Reagents—(1) Stored oxalated human plasma. Blood is collected by venepuncture from a normal person, mixed with 1/10 volume of sodium oxalate 0·1 *M*, and centrifuged for 10 min. at 2000 r.p.m. The supernatant plasma is transferred to open glass test-tubes kept at 4°C for a minimum of 15 and a maximum of 25 days. This period is specified because there is a negligible depletion of the labile factor during the first 2 weeks of storage and after 25 days prothrombin begins to be inactivated and fibrinogen denatured. Citrated human plasma should not be used, because it maintains a high concentration of labile factor for a long time.

(2) Human or rabbit brain thromboplastin, prepared according to Quick (1945)

(3) Calcium chloride, 0·02 *M*

(4) Sodium oxalate 0·1 *M*

Method—By venepuncture 4 5 ml. of the blood to be examined is collected and added to 0·5 ml. of sodium oxalate 0·1 *M* The plasma is obtained by centrifugation at 2000 r.p.m. for 10 min. With a pipette graduated to 0·01 ml. 0·09 ml. of the stored plasma is added to 0·01 ml of the plasma under examination in a 'Pyrex' test-tube (130 mm. × 10 mm.) and the prothrombin time of the mixture determined. It is advisable to use plasma from a healthy subject as a control and run the test within one hour of collection of the plasma.

Calculation.—The percentage of labile factor present in the plasma under examination is calculated directly from the prothrombin time obtained, by means of a dilution curve (fig 1) The dilution curve is constructed as follows decreasing volumes of fresh normal oxalated plasma are mixed with increasing volumes of saline solution to obtain known concentrations of labile factor from 100 to 10%, 0·1 ml. of each dilution is added to 0·09 ml. of stored plasma, and the prothrombin time of the mixture determined. The average analytical values obtained are as follows

Concentration of labile factor (%)	100	90	80	70	60	50	40	30	20	10
Prothrombin time (sec.)	20 2	21·6	22 1	23 5	25·6	28 3	31·4	35 2	40 7	50 2

Definition of labile factor activity, prothrombin activity, and prothrombin concentration, and meaning of their values as expressed in percentage have been discussed at length in a previous paper (Stefanini 1950a)

RESULTS

In Liver Dysfunction and Obstructive Jaundice

The 32 patients in this group included 4 with obstructive jaundice, 14 with Laennec's cirrhosis, 6 with chronic hepatitis, 5 with infective hepatitis, 2 with cardiac cirrhosis, and 1 with pigmentary cirrhosis. The degree of liver dysfunction was determined in each case on the basis of the clinical findings and the result of liver function tests (total serum-protein and A G ratio, serum-cholesterol and cholesterol esters level, bromsulphthalein retention, cephalin-cholesterol flocculation test, thymol turbidity test, serum-alkaline phosphatase, &c.)

The activity of the labile factor was normal in obstructive jaundice and always strikingly depleted in patients with impaired liver function The depletion of labile-factor activity did not parallel the behaviour of any of the liver-function tests but seemed to parallel roughly the serum-protein level. The importance of the level of labile-factor activity as a criterion of differentiation between obstructive and parenchymatous jaundice has been emphasised by Owren (1949), Harrington et al (1950), and Stefanini and Crosby (at the International Congress of Hæmatology in 1950), and is confirmed by the present findings. Owren also considers the activity of labile factor as an important prognostic sign and although more observations of this type are required, we also feel that in extremely severe liver dysfunction the progressive depletion of the labile factor more or less parallels the progressive functional failure of the hepatic parenchyma.

Little information is available at present on the site and the mechanism of synthesis of the labile factor in the body It was therefore decided to study the effect of vitamin K (material essential for the building of the prothrombin molecule) on the synthesis of the labile factor Of 28 cases of liver dysfunction 18 were selected for this study in whom the intravenous administration of synthetic vitamin K ('Hykinone,' Abbott, 70 mg) was followed by a significant increase in the plasma-prothrombin activity within twenty-four hours. The plasma labile-factor activity remained practically unmodified in all, as shown in fig 2, which illustrates a typical experiment. These results could be criticised on the ground that they were obtained in patients whose ability to synthesise prothrombin in the liver was impaired in part (the greatest effect of vitamin K occurred usually after twenty-four instead of four hours, as in cases of obstructive jaundice with preserved liver function) They indicate, however, that in all probability the synthesis of the labile factor takes place in the liver but does not require vitamin K

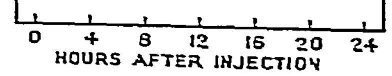

Fig 2—Typical increase in prothrombin activity with almost unaltered activity of labile factor of plasma after a large intravenous dose of vitamin K in cirrhosis of the liver with moderately affected liver function. Interrupted line represents response of level of prothrombin activity in a patient with obstructive jaundice, given for comparison. The patient received a dose of 70 mg of water-soluble vitamin K (Hykinone Abbott) intravenously

ACTIVITY OF PLASMA LABILE FACTOR IN DISEASE*

MARIO STEFANINI †
M D Rome, M Sc Marqueth
INSTRUCTOR IN MEDICINE, TUFTS COLLEGE MEDICAL SCHOOL, BOSTON, ASSISTANT PHYSICIAN, NEW ENGLAND CENTER HOSPITAL, BOSTON, MASS , U S A

THAT the formation of thrombin requires another plasma factor besides the three postulated in the classical theory of Morawitz (prothrombin, thromboplastin, and calcium) was first suggested by Nolf (1908) Quick (1943) gave the first convincing evidence of the existence of this factor, which he called at first "component A" and later "labile factor" (Quick 1947) Independently, Owren (1944) described a similar factor, which he called "factor V," and a hæmorrhagic condition due to its deficiency Fantl and Nance (1946) described an "accelerator factor" and Ware et al (1947) a "plasma Ac globulin" Owren (1948), Fantl and Nance (1948), and Ware and Seegers (1949) think that these last three factors are probably identical with the labile factor of Quick (1947)

The properties of the labile factor have been summarised as follows by Quick and Stefanini (1949a)

1 It is a normal globulin constituent of plasma and serum, and disappears fairly rapidly from human oxalated plasma stored at 4°C in oxygen or in atmospheric air The depletion of the factor during storage is much less in citrated or in native plasma (Stefanini 1948), being usually related to the concentration of calcium left in the plasma (Quick and Stefanini 1948b)

2 It is inactivated by heating at 58°C and is not adsorbed from oxalated plasma by various adsorbent gels thus making its separation from prothrombin relatively easy (Quick and Stefanini 1948b)

3 Its concentration varies from species to species, being very high in the rabbit, high in the dog, and comparatively low in man (Quick and Stefanini 1948a) Its concentration is not decreased in the hypoprothrombinæmia induced by dicoumarol or by vitamin K deficiency

4 Deficiency of the labile factor is indicated by a prolonged plasma prothrombin time and may be responsible for a severe hæmorrhagic diathesis (Owren 1947b) which can be controlled only by the transfusion of *fresh* blood or plasma

The labile factor is obviously a key substance in the formation of thrombin Ware and Seegers (1948) believe that it is strictly catalytic, whereas Quick and Stefanini (1950) suggest that it takes part in the formation of thrombin in stoichiometric relationship with prothrombin, calcium, and thromboplastin, since the concentration of labile factor in the plasma seems to determine the amount of prothrombin utilised during coagulation In further support of this view Stefanini and Crosby (1950b) have shown that the amounts of prothrombin and labile factor utilised during the coagulation of blood in normal and abnormal conditions are in close quantitative relation Owren (1947a) has found that thrombin cannot be formed in the absence of "factor V" It is admittedly difficult to analyse a reaction (the formation of thrombin from prothrombin) which intervenes between two enzymatic reactions—the activation of thromboplastin and the formation of fibrin

Other work suggests another possible action of the labile factor in the coagulation of blood Ware and Seegers (1948) have postulated that their "plasma Ac globulin" is activated by thrombin to a "serum Ac globulin," a much more powerful accelerator of the formation of thrombin This finding has been extended to man by Stefanini and Crosby (1950a), who also reviewed the importance of these results and their interpretation in the light of our present knowledge of blood coagulation at the International Congress of Hæmatology at Cambridge in 1950

In view of the obvious importance of the labile factor in the formation of thrombin it is somewhat surprising that only fragmentary and isolated studies have appeared on the variations of the labile factor in diseases characterised by bleeding and/or a prolonged prothrombin time. Perhaps one of the reasons for the lack of such studies is the difficulty of determining the activity of the labile factor accurately I have introduced a quantitative technique for determining its activity in plasma (Stefanini 1950a) and in serum (Stefanini and Crosby 1950b) By this method the activity of the labile factor has been determined in a large number of patients and the results are reported here The values so obtained have been compared with the activity and concentration of prothrombin in the plasma, to investigate the importance of the depletion of the labile factor in determining the prolonged prothrombin time in various diseases

MATERIALS AND METHODS

The present series (see table I) included 187 persons who had active bleeding or a prolonged prothrombin time and 15 cases of hypoprothrombinæmia induced by dicoumarol treatment Labile factor and prothrombin activity as well as concentration of prothrombin in plasma were determined in each case The values obtained were correlated with other clinical laboratory data

The activity of prothrombin was determined from the prothrombin time, both on undiluted and 10% diluted plasma, by the methods of Quick (1945) and of Tuft and Rosenfield (1947) respectively The purpose of the latter determination was to avoid errors due to possible changes in the concentration and reactivity of fibrinogen. The method of Tuft and Rosenfield was slightly modified by using as a diluent plasma deprothrombinised with $Ca_3(PO_4)_2$ gel (Quick and Stefanini 1948a) Concentration of prothrombin was determined *quantitatively* (Stefanini 1950a) by a method based on observations previously reported (Quick and Stefanini 1949a) The activity of the labile factor was determined by the method of

---

* Labile factor has been recently called 'plasma prothrombin conversion factor (P P C F)' by the author of this article His reasons for this change in terminology and the selection of the new word have been given in *Blood* (January 1951 p 84) Throughout this paper however the definition of 'labile factor' will be maintained to avoid confusion and indicate clearly the method of assay used for the quantitative determination of the factor

† This work was completed during the tenure of a Damon Runyon senior clinical research fellowship administered by the American Cancer Society and was aided by grants from the Charlton Fund and the American Cancer Society *Massachusetts Division* It was done in the Ziskind Laboratories (hematology section) Joseph H Pratt and New England Center Hospitals and the Department of Medicine *Tufts College* Medical School

After Major Operations

15 patients were studied in the fourteen days following major surgical operations splenectomy for various causes in 7, neurosurgical procedures in 3, cholecystectomy in 2, total hysterectomy in 1, nephrectomy in 2 Only patients with good postoperative liver function were studied The results presented here were somewhat influenced by the administration of fresh bank blood which, because of the presence of sodium citrate in the approximate concentration of 0 18 *M* in the anticoagulant fluid, exhibited good labile factor activity (Quick and Stefanini 1948b) As indicated in fig 4, which presents the average results obtained in the 15 cases, while the activity of prothrombin remained substantially unmodified and normal, that of labile factor much decreased immediately after the operation, reaching its lowest level on the third day and slowly returning to normal on the ninth day The behaviour of the labile factor appeared largely independent of that of total protein and its different fractions and that of fibrinogen. The level of fibrinogen reached the highest peak on the third postoperative day, the time at which the labile factor activity of plasma was at its lowest level.

DISCUSSION

Little is known at present about the mechanism of production of labile factor in the body Sykes et al. (1948) have observed depletion of "plasma Ac globulin" after liver injury in dogs The decrease of plasma labile factor activity observed by Owren (1949) and Harrington et al. (1950) and reported by me (Stefanini 1950a) also confirms the important rôle of the liver in the synthesis of labile factor Further proof comes from the rough relation repeatedly found between depletion of labile factor activity and fall in serum protein level. It is, however, a moot question whether the liver is the only organ in which labile factor is produced, for we have shown that this factor can be depleted in those cases of acute leukæmia, pernicious anæmia, and sprue, in which no liver dysfunction can be demonstrated. Though the solution of this and other questions will have to await further investigation, the most significant information obtained from the clinical observations presented here is probably that no vitamin K is required for the synthesis of the labile factor in the body

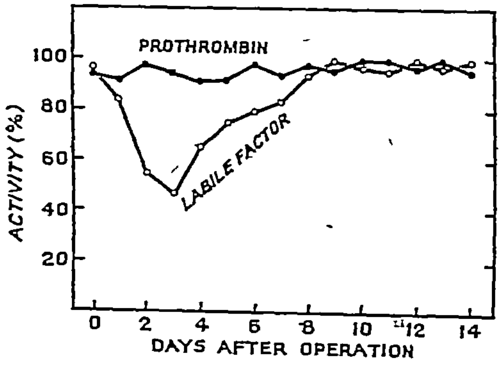

Fig. 4—Comparative behaviour of prothrombin and labile-factor activity in immediate postoperative period. *Curves represent average of results in 15 cases.*

The present findings also confirm previous conclusions (Stefanini 1950a) that an isolated depletion of plasma labile factor activity without associated depletion of prothrombin activity is seldom found. According to our studies this situation occurs only in rare congenital cases, like the one described by Owren (1947b) under the debatable term of "parahæmophilia," and after operation. More often the deficiency of labile factor is associated with that of prothrombin. This observation emphasises the need for separate assay of prothrombin concentration and labile factor activity in every case of hypoprothrombinæmia (Stefanini 1950a) It also raises a number of practical points, the most important of which is obviously the choice of blood to be used in case of hæmorrhage in patients with hypoprothrombinæmia. It is evident that only fresh blood should be used to render normal the clotting-mechanism of patients when plasma labile factor activity is depleted. The use of fresh blood is even more imperative in patients with associated platelet and labile factor deficiency (acute leukæmias), where only blood freshly drawn (2–4 hours) will temporarily render the hæmostatic mechanism normal.

The observation that labile factor activity is not depleted during dicoumarol treatment is of considerable importance Ever since the importance of the labile factor in the formation of thrombin has been recognised, the one-stage procedure for determining the prothrombin-time of Quick has been criticised as inaccurate technique of control of dicoumarol therapy It is argued that the method would not distinguish between changes in the concentration of prothrombin and activity of labile factor

It must be admitted that, theoretically at least, the most accurate test for the control of dicoumarol therapy is one which will accurately indicate the changes of prothrombin only Our results indicate that no changes in the activity of plasma labile factor can be demonstrated during dicoumarol therapy, Fahey et al. (1948) and Olwin (1949) also agree that changes in concentration of "plasma Ac globulin" revealed by two stage methods in the course of dicoumarol therapy are limited in extent and quite transitory The obvious conclusion is that the one-stage procedure of Quick is a safe and accurate method of controlling anticoagulant therapy It may be added here that, in the course of dicoumarol treatment, the results of the Quick one-stage method for the determination of prothrombin activity of plasma and those of the test recently introduced (Stefanini 1950a) for the direct calculation of concentration of plasma prothrombin have thus far agreed within ± 5%

The significance and importance of the depletion of plasma labile factor in the immediate postoperative period remain to be assessed. Observations are in progress to establish whether this is a constant finding and what relationship it has, if any, to the thrombotic tendency known to occur after operation. It is quite possible that the depletion of plasma labile factor might be due to the loss of blood during operation and its substitution with bank blood, which contains a suboptimal concentration of labile factor A contemporary transitory liver dysfunction, due to the stress of undergoing operation, would explain the slow regeneration of the factor by the liver It is common clinical observation that thrombosis appears late in the postoperative course, always after the second or third postoperation day It might be interesting to speculate at this time whether thrombosis in the early postoperative period is prevented by the existing depletion of plasma labile-factor activity

SUMMARY

By a simple method the labile factor activity of plasma was determined and compared with plasma-prothrombin activity and concentration in a large number of patients, including cases with active bleeding or a delayed prothrombin time

A significantly depleted activity of plasma labile factor was consistently found in liver dysfunction, thrombocytopenia of acute leukæmia and other hæmatological disorders, hypoprothrombinæmia of terminal carcinoma, and the immediate postoperative period

In liver dysfunction large doses of vitamin K did not restore to normal levels the plasma labile-factor activity

Hæmorrhagic Conditions

Plasma prothrombin and labile factor activity were determined in 117 cases of different hæmorrhagic conditions Labile factor activity was normal in all cases in which dysfunction of the vascular factor of hæmostasis is known, or assumed, to be responsible for the hæmorrhagic manifestations Vascular purpuras of various types, hereditary hæmorrhagic telangiectasia, and anaphylactoid purpura belong to the first group, polycythæmia vera to the second In pseudohæmophilia, a familial condition characterised by a prolonged bleeding-time in the absence of other abnormalities of the hæmostatic mechanism (Estren et al 1946), plasma labile factor activity was also normal

No substantial depletion of labile factor activity was found in 9 cases of thrombocytopenic purpura, idiopathic and allergic, and in 1 case of thrombo asthenia These results agree with the experimental observation that decrease in the number of platelets brought about in normal plasma by centrifugation does not affect the determination of labile factor activity In the experiment shown in table II normal plasma aliquots were centrifuged for various periods at different speeds to produce various diminutions of the number of platelets Since all the experiments were conducted in silicone coated containers, it is highly improbable that liberation of platelet products influenced the results 36 cases of symptomatic thrombocytopenia were examined, most of the patients having acute leukæmia of the lymphocytic, myelocytic, and monomyelocytic variety Only 1 presented evidence of a heparin like circulating anticoagulant (Allen et al 1947) and was therefore excluded from the series The remaining 35 presented a striking depletion of labile factor activity When compared with the results obtained in our cases of idiopathic thrombocytopenic purpura, this finding suggests that the depletion of labile factor activity in these cases is not due to platelet deficiency but rather to something else, such as impaired synthesis of the factor by an inefficient liver Against this conclusion, however, is the depletion of prothrombin in both idiopathic and symptomatic thrombocytopenic purpura Further studies are now in progress

Labile factor activity was normal in hæmophilia, even immediately before and during spontaneous bleeding episodes On the other hand, an interesting observation was made in this disease, which might be of some importance in explaining the mechanism of bleeding The clotting time of whole blood was prolonged and the prothrombin activity significantly decreased for about a week preceding and a week following the episode of active bleeding (fig 3) This observation was made in only 2 cases being followed routinely and requires further confirmation

TABLE II—INFLUENCE OF NUMBER OF PLATELETS ON PROTHROMBIN AND LABILE FACTOR ACTIVITY AND CONCENTRATION OF PROTHROMBIN IN HUMAN PLASMA * IN A TYPICAL EXPERIMENT

No of sample	Platelets per c mm	Labile factor activity (%)	Prothrombin activity (%)	Prothrombin concentration (%)
I	4000	100	100	95
II	55 000	95	96	90
III	115 000	95	92	92
IV	474 000	90	100	96

* All samples were collected by a two-syringe method (Stefanini 1950b) in syringes coated with silicone and transferred to chilled test tubes also coated with silicone Depletion of platelets in plasma was determined by centrifuging the different samples of blood at different speeds for various times sample I for 20 minutes at 3000 r p.m sample II for 5 minutes at 1500 r p m and sample III for 2 minutes at 1500 r p.m Sample IV was allowed to sediment spontaneously for 30 minutes in the cold

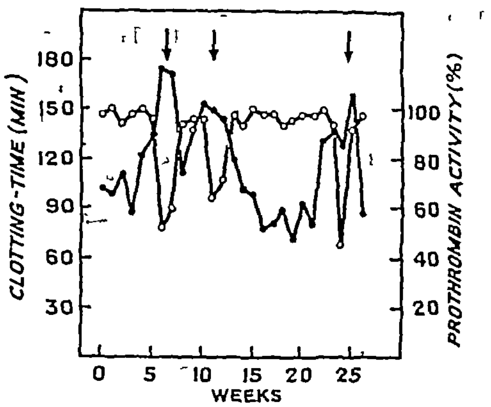

Fig 3—Behaviour of clotting-time (black dots) and plasma-prothrombin activity (white dots) in a hæmophiliac, determined at weekly intervals for six months. Three episodes of spontaneous bleeding (indicated by arrows) were preceded by prolongation of clotting-time and depletion of prothrombin activity Both changes were temporary

In Hypoprothrombinæmia of the Newborn

In disagreement with observations of previous workers, Randall and Randall (1949) gave evidence that no deficiency of known "accelerators" of the conversion of prothrombin to thrombin could be substantiated in hypoprothrombinæmia of the newborn From indirect findings they concluded that hypoprothrombinæmia of the newborn was due to depletion not only of prothrombin but also of an accessory unknown factor favouring the formation of thrombin In our 7 cases of hypoprothrombinæmia of the newborn the labile factor activity of plasma was only slightly depleted, whereas plasma prothrombin activity was much reduced during the third day after birth However, the percentage of concentration of plasma prothrombin, determined by the method recently described (Stefanini 1950a), was significantly higher than that of plasma prothrombin activity The difference consistently observed between the values of the two constants, being the labile factor activity normal, suggests that the deficiency of another probably plasmatic factor besides prothrombin is responsible for the prolonged prothrombin time of the newborn. More work is in progress

In Dicoumarol Hypoprothrombinæmia

Quick and Stefanini (1949b) could not detect any change in labile factor activity of plasma in rabbits and dogs treated with dicoumarol Fahey et al (1948), however, found that a decreased concentration of "plasma Ac globulin" could be found in the early stages of dicoumarol treatment in laboratory animals The level quickly returned to normal even when the treatment was continued Essentially similar results were obtained in man by Olwin (1949) Olwin and Fahey et al used a two stage method of assay whereas Quick and Stefanini used a one stage method, hence the discrepancy of results among the various investigations is very likely due to [illegible] different methods Our finding, obtained with the one stage method described here, confirms that no appreciable changes in labile factor activity estimated daily can be observed in man during dicoumarol therapy Of our 15 cases, in 12 the labile factor activity of plasma was determined on the fourth day of therapy, and in the remaining 3 was followed daily for thirty days.

In Terminal Carcinoma

In 12 cases of terminal carcinoma the labile factor activity was consistently reduced, along with the activity and concentration of prothrombin in plasma. The decrease of plasma labile factor activity was roughly parallel to the depletion of serum protein of these patients when initially seen forty eight hours before death this child seemed to have pneumonia, its respirations being rapid, inverted, and associated with working alæ nasi, but at necropsy no lesions in the lung were found

The fatal cases (1, 2, and 4) all developed a spinal block

Necropsy Findings

At necropsy cases 1, 2, and 4 all presented a similar picture in the central nervous system Both cerebral hemispheres were almost covered, and the spinal cord was encased, in tenacious yellow green pus In case 1 the exudate was bacteriologically sterile

Laboratory Findings

In all the cases the strains of *H influenzæ* isolated were type b The sensitivities for streptomycin was 2–10 units per ml. and for penicillin 1–10 units per ml. In cases 1, 3, 6, and 7 the cerebrospinal fluid (C.S.F) became sterile in twenty four hours No streptomycin resistant strains developed in any of the cases The C S.F streptomycin levels twenty-four hours after an intrathecal injection of 25–50 mg of streptomycin were 4–64 units per ml.

Sibling Relationship

Ounsted (1950) found that the 13 children with influenzal meningitis he had treated all had two or more older sibs under the age of 12 years He concluded ‘ It seems possible that the *H influenzæ* organisms require one or two bacterial passages through partially immune contacts before a strain is evolved that can pass the meningeal barriers ” In our cases the ages of the children in the family were as follows, sibs under the age of 12 years being shown in italics

TABLE III—AGE INCIDENCE OF INFLUENZAL MENINGITIS IN 104 CASES REPORTED IN GREAT BRITAIN IN TEN YEARS

Age	No recovered	No died	Total no

22–35	4	2	2
Total	104	68	36

* Two patients became demented.

Thus in 4 of our 11 cases there were two or more sibs under 12 years Ounsted (1950) compared his figures with those for cases of meningococcal meningitis and found a significant difference In the 21 cases of meningococcal meningitis in children below the age of 2 years treated in Leeds General Infirmary during the same period as our series the number with two or more sibs under 12 years was 3

DISCUSSION

The diagnosis of *H influenzæ* meningitis is made particularly difficult by the age of the patients Of 104 cases in the British Isles in the past ten years 88 were under the age of 3 years (table III) This age group is characterised not only by a paucity of comprehensible expression but also by an uncoöperativeness compounded of fear and negativism In this country cases of *H influenzæ* meningitis are rare in one physician's experience, since there never has been an epidemic of the condition Smythe (1948) drew attention to two types of severe case (1) a short fulminating illness, and (2) a subacute type which tended to deteriorate into a critical state Of the 104 cases mentioned, 28 (about a quarter) had their first lumbar puncture on or after the eighth day of illness (table IV) There were 13 deaths in this group and 2 children became demented, giving a recovery-rate of 47% The only way of improving the outlook in this group is by earlier diagnosis

In some cases the symptoms did not suggest meningitis 5 children presented with a gastro intestinal syndrome and 16 others with symptoms of upper respiratory infection When upper respiratory infections are prevalent it is not easy to detect that a feverish cold is due to a more serious infection Still more difficult is it to revise an established diagnosis On the other hand, meningism and convulsive phenomena should be accorded the respect that their possible ætiology warrants A diagnosis of teething as a cause of fits is likely to be

I.M = intramuscular I T = intrathecal

in those cases in which the prothrombin activity was restored to normal, indicating that, though the labile factor is probably produced in the liver, vitamin K is not requred for its synthesis

No changes in labile factor activity were noticed during dicoumarol therapy

Two additional findings of importance were made in the course of this investigation (1) suggestive evidence that the deficiency of an additional unknown plasma factor plays a definite part in the pathogenesis of the hypoprothrombinæmia of the newborn, and (2) a constant exaggerated delay of the clotting time and depletion of prothrombin activity in the week immediately preceding and that following spontaneous bleeding episodes in hæmophilia Labile factor activity of plasma was normal in both conditions

MOST reports on the streptomycin treatment of *H influenzæ* meningitis published in this country (Wilson 1948, Smythe 1948, Roscoe and Gleeson-White 1948) have emphasised that failure is usually due to the rapid development of streptomycin resistance in the infecting organism This feature was not encountered in our series, where failures of treatment were due to other causes Ounsted (1949), in his 10 cases, did not observe drug fastness either, nor did he have to deal with more than one case of the subacute type (Zinnemann 1946, Smythe 1948) The generally poor prognosis in the subacute type of case is only mentioned in passing in one of the reports cited (Smythe 1948) Alexander et al (1946) emphasised that intensive treatment of subacute cases with streptomycin might lead to survival, but with serious and permanent cerebral damage These cases seem worthy of particular attention because if efforts were intensified to diagnose them earlier the prognosis would be considerably brightened (Alexander 1943, Jones 1947)

TABLE I—CLINICAL DETAILS OF 11 CASES OF *H Influenzæ* MENINGITIS

Case no	Age (mos)	Presenting symptoms	Clinical severity	Duration of illness before admission (days)	Period between admission and 1st lumbar puncture (days)	Total period before meningitis suspected (days)	Duration of treatment (days)	Result
1	4	Meningismus	Severe	7	0	7	7	Death
2	13	Gastro enteritis	Severe	1	6	7	9	Death
3	12	Gastro enteritis	Moderate	7	6	13	7	Cure
4	22	Vomiting	Severe	5	0	5	1	Death
5	12	Upper respiratory infection	Severe	7	2	9	60	Dementia, blindness, hydrocephalus
6	8	Meningismus	Moderate	6	0	6	15	Cure
7	15	Convulsion	Severe	2	0	2	12	Cure
8	18	Vomiting	Severe	5	0	5	22	Cure
9	6	Upper respiratory infection meningismus	Moderate	4	2	6	17	Cure
10	15	Meningismus	Severe	3	0	3	12	Cure
11	19	Listlessness, upper respiratory infection	Moderate	21	9	30	20	Cure

The following 11 cases (tables I and II), treated at the Leeds Streptomycin Clinical Trials Centre in the last two years, illustrate some of the difficulties of early diagnosis

Presenting Symptoms

Only 5 of the 11 cases showed presenting symptoms suggesting involvement of the central nervous system Cases 2, 3, and 4 were thought to have gastro enteritis, and cases 5 and 11 an upper respiratory infection As a result, diagnostic lumbar puncture in these cases was delayed for 5–30 days after the onset of the illness

Antecedent Manifestations

In 4 of the histories there were antecedent manifestations, the significance of which is problematical but which may have some bearing on the subsequent development of the disease Case 1 had a persistent cough for a month before admission Case 5 was admitted to hospital fifteen days before the final admission, was treated for an upper respiratory infection, and was discharged the day before the onset of what was at first considered to be a relapse Cases 2 and 6 had a head injury—in case 2 the fall was on the forehead six days before the onset and the child subsequently continued to rub its head up to the start of gastro enteritic symptoms, and case 6 fell out of bed twelve hours before the start of symptoms

Complications

On admission case 1 had a fluctuant swelling 2 cm in diameter at the right lateral angle of the anterior fontanelle, at necropsy this was found to be a herniation from the subarachnoid space full of tenacious yellow green pus On the day of admission case 4 developed a painful swelling of the left elbow joint and left knee joint, necropsy confirmed a purulent arthritis In case 10 a swollen left knee was detected on the second day in hospital Cases 3 and 7 had congestion of the tympanic membranes Case 4 had bilateral purulent otitis media, of a drip glucose transfusion, which was maintained for some time after the nitrogen mustard had been given

URETHANE

Paterson et al. (1946) first reported the use of urethane in the treatment of leukæmia and, at the end of this report, stated that urethane had also been given to a few patients with advanced carcinoma without any degree of success The dosage used was 3–5 g daily by mouth

Haddow and Sexton (1946), working with the Walker rat carcinoma, found that urethane, given intraperitoneally in a dosage of 0 25–0 5 g per kg of body weight, produced very pronounced cytological changes in implanted tumours and pronounced inhibition of tumour growth

Urethane was also shown to be capable of inducing tumour growth, and Henshaw (1945) and Larsen (1946) showed that urethane could produce pulmonary adenomata in mice Orr (1947) has shown that the first effect of urethane is to set up inflammation in the lungs of mice, and that the adenomata seem to come as a result of further changes in the inflammatory lesions

My work with urethane began in 1946 in the department of surgery in the University of Liverpool, when, because of the apparent affinity of urethane for bronchial epithelium, I treated patients with inoperable carcinoma of the bronchus with large doses of urethane Two patients with this condition and two patients with inoperable carcinoma of the breast were treated. The results were very unsatisfactory Acute hæmolysis developed in two cases, jaundice occurred in all, and in biopsy specimens in three cases before and after treatment no change was seen in the cell picture In the first case (carcinoma of bronchus) urethane was given intravenously in doses of 28 g daily, and, although the patient died from pyæmia seven days after treatment had begun, at necropsy both primary and secondary growths were found to be completely necrotic This case and the third case, which came to necropsy also, showed subacute necrosis of the liver

The further use of urethane was therefore postponed for an indefinite period, and not until I came to Hong-Kong did I resume this work All patients with nasopharyngeal carcinoma were regarded as beyond hope of other treatment, and consequently high and potentially dangerous dosage of this toxic drug was considered justifiable For administrative convenience the daily dose was standardised at 10 g dissolved in 20 ml. of water, which in the average patient weighing about 40 kg approximated to Haddow and Sexton's (1946) minimal dosage in rats—i.e, 0 25 g per kg of body-weight

An intravenous drip transfusion of 5% glucose in water was set up, and, after it had been running for a few minutes, the whole dose of urethane was injected into the tube The urethane was then washed through the vein quickly and the drip continued until 1000 ml. of 5% glucose had been given The immediate results of treatment are given in the accompanying table, and are summarised as follows

Died in hospital	5	
Refused adequate treatment	5	
No improvement	4	
Slight improvement	4	(2 untraced after 4 and 6 months 1 recurred after 4 months 1 died within 3 months)
Great improvement	5	(1 recurred after 6 months 1 died after 4 months cause unknown 1 large recurrence after 2 months 3 too recent to follow up)

"Great improvement" means disappearance of the primary or the secondary mass, or both "Slight improvement" means diminution in size of the mass and usually increased mobility

The follow-up period is very short, and the difficulties of following up patients in a shifting and overcrowded community like that of Hong-Kong are considerable It is felt, however, that the initial results of this investigation are of considerable significance, because this tumour does not regress spontaneously Apart from those five cases in which treatment was hopelessly inadequate, a noticeable improvement occurred in nine out of eighteen cases, and very great improvement—i e, disappearance of the tumour—in five out of eighteen

We do not yet know how long the remission will last, but, since the earliest cases in the series already show signs of recurrence, urethane seems to give temporary benefit only Possibly a combination of urethane and radiotherapy may hold out greater hopes of permanent relief, but this has not yet been tried here

Urethane given in this way is far from pleasant, and there is evidence of considerable toxicity Anorexia, nausea, and vomiting invariably develop, and patients vary a good deal in the way in which they react to this A soft or fluid diet with glucose drinks will usually be tolerated. In this series jaundice occurred only three times In two patients this was just before death, and in these two patients there was no evidence of subacute necrosis of the liver In the third patient (case 23) the dosage of urethane was increased, after six doses of 10 g daily, to 15 g daily for the next six doses The white cell count fell sharply, and jaundice followed three days after the end of treatment Jaundice persisted, and at peritoneoscopy on July 29, 1950, the liver was seen to be finely granular Biopsy was not done, and the patient's condition was deteriorating rapidly The effect in the white cell count is very variable Often in the first few days the total count rises to about 12,000 cells per c mm and thereafter falls slowly, but this change is not constant, and, when a patient receives two courses of urethane—e g, case 22,—the white cell count may fall on the first occasion, recover in the interval, and not fall at all in the second course In other cases there is no initial rise but a steady and progressive fall in the total count, polymorphs, and lymphocytes being equally attacked

SUMMARY

Haddow and Sexton (1946) have shown that urethane in large doses partially inhibits the growth of implanted tumours in animals, slowing down the growth but not completely stopping it

A similar effect has now been demonstrated in man with nasopharyngeal carcinoma, when on certain occasions very great diminution in size has been noted as a result of high dosage of urethane intravenously

So far as can be foreseen at present, the effect is only temporary, for in most cases where some benefit has been shown the tumour has recurred fairly rapidly

"I think that the next thing that the public expects the medical profession to do is to recognise that the subject of medical care is not the exclusive domain of the medical profession It is the primary concern of every citizen. All too often the medical profession leaves the impression that it regards the discussion of a medical problem by a non-medical speaker or writer as an unwarranted interference with the practice of medicine "—L B SELTZER, *J Amer med Ass* 1950, 114, 1573 wishful thinking We endorse the plea of Alexander (1943) for earlier and more frequent lumbar puncture in any case of fever accompanied by meningeal irritation

Our figures for sibling relationship do not bear out the hypothesis of Ounsted (1950), but it was interesting to find that only 5 of the 104 British cases collected in the last ten years were in children under the age of 6 months

SUMMARY

Eleven cases of *H influenzæ* meningitis treated with streptomycin are reported to illustrate the difficulties of diagnosis in young children and the poor prognosis in cases where treatment is started in the advanced stages

The causes of therapeutic failure are discussed

Earlier diagnosis by lumbar puncture is essential if the results are to be improved

NITROGEN MUSTARD AND URETHANE IN THE TREATMENT OF NASOPHARYNGEAL CARCINOMA

FRANCIS E STOCK
M B Lond, F.R C S, D T.M & H
PROFESSOR OF SURGERY IN THE UNIVERSITY OF HONG KONG

ADEQUATE clinical descriptions of nasopharyngeal carcinoma have been published from time to time, and an excellent and profusely illustrated description of the condition as seen in Hong-Kong was published by Digby et al (1941) Virtually nothing, however, is known of its ætiology, despite the fact that it is the most common type of carcinoma encountered in Hong-Kong and South China

The age incidence is very wide In the short series recorded here the average age was 37, seven patients being aged 30 or less, and nine being aged 40 or more

Treatment of the condition is extremely unsatisfactory Radical surgery is impracticable because of the primary site of the tumour and because in most cases large fixed glands are present when the patient first appears. Mekie and Ransome (1950) have treated patients with advanced disease by prefrontal leucotomy with the idea of relieving pain, and this method is also being adopted here in selected cases Radiotherapy is in most cases only palliative, if indeed it has any effect at all, and with the present shortage of staff and equipment in the main government hospital in Hong Kong patients with nasopharyngeal tumour are not accepted for radiotherapy

Our interest in the treatment of this apparently hopeless condition has turned in other directions, and I report here the first attempts made in this department to combat this condition with specific carcinolytic drugs. Two drugs have been used in this series and they will be considered separately

NITROGEN MUSTARD

A series of 25 cases was started in May, 1949 The cases were entirely unselected but represented all the late stages of nasopharyngeal carcinoma In all the cases glands were available for section, and usually biopsy was done before treatment began and again at the end of treatment

This series is not reported in detail because, though in a few cases there was a very slight diminution in size of the glands, and in advanced cases with bone involvement a temporary decrease in the amount of pain experienced, in no case did this temporary remission last for more than four weeks, and in most cases no effect at all was seen in the tumour mass and there was no amelioration of symptoms The biopsies done before and after treatment showed no significant change in the cell picture The dosage of nitrogen mustard used was 0 1 mg per kg of body weight daily for six doses administered by direct injection into the tube

RESULTS OF TREATMENT OF NASOPHARYNGEAL CARCINOMA WITH URETHANE

Case no	Age (yr)	Sex	Daily dose (g)	Total dose (g)	Length of treatment (days)	Treatment ended	Immediate result	Follow up
1	34	M	10	150	48	Dec 14 1949	Great improvement	July 11, 1950, mass larger again
2	33	F	10	200	47	Dec 9 1949	No improvement	
3	30	F	10	160	60	Jan 24, 1950	Toxic reaction, slight improvement	June, 1950 untraced (returned to village)
4	36	F	10	150	35	Jan 12, 1950	No improvement	
5	49	M	10	100	16	Jan 3 1950	Died Jan 11, 1950	
6	25	M	10	60	22	Jan 23, 1950	Refused further treatment, nausea and vomiting considerable	
7	51	M	10	150	46	March 9, 1950	No improvement	
8	42	F	10	200	48	March 9, 1950	Slight improvement	July 11, 1950, mass much larger
9	55	F	10	130	34	Feb 25 1950	Developed toxic nephritis great local improvement	June 1950, died recently, cause unknown
10	33	M	10	10	1	Jan 23 1950	Severe vomiting, refused further treatment	
11	34	M	10	50	12	Feb 7 1950	Severe vomiting, refused further treatment	
12	45	M	10	20	3	Feb 6 1950	Severe vomiting refused further treatment	
13	19	M	10	200	64	April 28 1950	Severe reaction great improvement	June 1950 large recurrence
14	19	M	10	150	29	Feb 24, 1950	Slight improvement	June 1950 died recently
15	40	F	10	170	35	April 6 1950	Slight improvement	June 1950 untraced (returned to village)
16	51	F	10	150	25	April 24 1950	Died April 25 1950	
17	27	M	10	40	5	April 7 1950	Refused further treatment	
18	30	F	10	100	23	April 24 1950	Died April 27 1950	
19	47	F	10	130	15	April 30 1950	Died May 4 1950	
20	27	F	10	80	11	June 10 1950	Great improvement treatment discontinued when white cell count fell to 1000 per c.mm	
21	44	F	10	30	6	June 7 1950	Died after refusing further treatment	
22	38	F	10	170	17	May 3 1950	Great improvement	
			10	100	9	June 8 1950		
23	36	M	10	150	12	June 7 1950	No improvement	
			15			June 13, 1950	Jaundice and ascites	

fever, the patient was given an intravenous injection of cardophylin 0·48 g with no effect

In an attempt to obtain diuresis without the reactions the patient was given tablets of mersalyl by mouth, in 80 mg 160 mg and 320 mg doses a day for 1, 4, and 5 days respectively, with no fever or diuresis

Dimercaprol was tried in the hope that it might abolish the reactions and leave some diuretic effect The patient was given three intramuscular injections of 100 mg at 6 and 10 A.M. and 2 P.M. At 10 15 A.M. he was given neptal 0·25 ml intramuscularly At 1 30 P.M. he was very miserable, complaining of pain in his limbs and back, irritation of his skin, and a sensation of heat on the top of his head He was shivering and cyanosed but developed no fever A few days later he was given a similar injection of neptal without the dimercaprol, and the reaction was indistinguishable from the previous one

In view of the gross subjective disturbance it was not thought justifiable to pursue the question of sensitivity further

COMMENTS

These two cases illustrate a pyrexial reaction to mercurial diuretics after 6–10 days The fever and subjective symptoms increased daily Different brands of mercurial drugs with slightly different molecular structure produced identical responses, and oral administration caused fever in one case but no effect on temperature or diuresis in the second. Dimercaprol (B A.L.) was tried and had no effect, but an insufficient amount seems to have been given before the neptal (Sussman and Schack 1947)

Both of the present patients showed a heightened reaction to intradermal injections of these drugs compared with controls

We wish to thank Prof E P Sharpey-Schafer for permission to publish these two cases

URTICARIA FOLLOWING ADRENALINE BUT NOT NORADRENALINE

H. HERXHEIMER
L.R.C.P.E
CLINICAL AND RESEARCH ASSISTANT UNIVERSITY COLLEGE HOSPITAL, LONDON

URTICARIA is usually suppressed by adrenaline There seems to be only one case on record of urticaria produced by an injection of adrenaline (Dumm 1941), this patient reacted only to natural adrenaline, and the rash could not be provoked by synthetic adrenaline An intriguing feature of the case described below was the strikingly different effect of adrenaline and noradrenaline

A man, aged 33 had suffered from asthma and urticaria since 1944 when he served with the R.A.F in Egypt In 1945 he was given an adrenaline injection for his asthma, a short time later he had severe palpitations followed by an urticarial rash all over his body while the asthma subsided The same occurred after a second injection of adrenaline and again when he was given ephedrine tablets He had since avoided these drugs

In December 1949 when the patient came under observation at University College Hospital his asthma was mild and the urticaria appeared only occasionally An asthmatic attack could be induced by letting him inhale mould extract or pollen extract whereas the urticaria was precipitated by the emotions such as fear or vexation.

The patient was given 1 minim of synthetic adrenaline 1 1000 subcutaneously after 5 minutes he noted mild palpitations and after 30 minutes an urticarial rash appeared on his arms trunk, and legs This reaction could be prevented by giving 150 mg of the anti histamine drug 'Chlorcyclizine' by mouth one hour before the adrenaline injection. A subcutaneous injection of 3 minims of adrenaline produced a similar rash but this could not be completely prevented by chlorcyclizine When the man received 200 mg of chlorcycline by mouth, and then, after an interval of an hour, 5 minims of adrenaline subcutaneously, the rash appeared 15 minutes later Subcutaneous injections of either 1 or 3 minims of noradrenaline did not produce any rash. An injection of sodium metabisulphite solution, which is usually added to commercial adrenaline solutions as a "stabiliser," did not cause any urticaria, whereas adrenaline containing none of this substance still produced the rash. When the man inhaled 2% isopropylnoradrenaline aerosol tachycardia and palpitations developed, but no rash appeared.

No further investigations could be carried out in this case because the patient left London

I am indebted to Dr Norman Whittaker and Dr V Davies for referring this case to me

LICHEN STRIATUS

HAROLD LEE
M.D Leeds
SENIOR REGISTRAR DERMATOLOGICAL CLINIC, NOTTINGHAM

LICHEN striatus is a relatively rare condition which usually occurs in children in the form of a linear lichenoid papular eruption (Ormsby and Montgomery 1948) Generally the arms are involved, and the condition commonly is unilateral. The onset is sudden, and the extension of the eruption to form linear bands is rapid. These bands are composed of small lichenoid papules, which often coalesce to form regions of lichenified dermatitis As a rule there are no subjective symptoms.

Senear and Caro (1941) drew attention to the condition and reviewed the literature Since then a few cases have been reported in America, but hitherto none in Great Britain

CASE RECORD

A girl aged 8 years was first seen on July 15 1949 with a history that some eight weeks previously she had developed german measles (rash on face and body with cervical adenitis), and when this cleared she had become aware of a rash on the left mid-calf This rash had spread quickly in the form of a line up and down the limb

On examination there was a continuous line of lichenoid papules extending from the topmost part of the left thigh downwards to behind the internal malleolus (fig 1) The band, which was about 1/4 in. wide and about 1 in. medial to the midline of the limb was slightly scaly behind the malleolus. No other lesions were present on the skin or the mucosal surfaces The band was completely asymptomatic. A biopsy specimen was taken from just above the knee flexure

Progress—The patient was next seen on Aug 11, 1949, when the eruption was beginning to fade Her mother reported that it had been even better at one stage, but had seemed to return again. On the next visit Nov 4, 1949 the eruption had faded completely, leaving no trace except a very little superficial scaling behind the malleolus

Histology

The histological report (Dr E A. Horne) was in keeping with the clinical diagnosis of lichen striatus

Epidermis (figs 2 and 3)—The epidermis showed some loose hyperkeratosis In some places possibly in association with follicular openings there was slight dipping of this layer The stratum granulosum was present throughout, but was considerably thinned—in some places not more than one

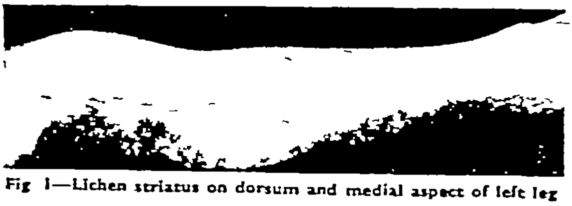

Fig 1—Lichen striatus on dorsum and medial aspect of left leg

SENSITIVITY TO MERCURIAL DIURETICS

REPORT OF TWO CASES

C A FOSTER
M B Lond

P F D NAYLOR
M A , M B Camb

HOUSE PHYSICIANS, ST THOMAS'S HOSPITAL, LONDON

REACTIONS to mercurial diuretics given intramuscularly are rarely reported, and their diagnosis is not always easy, as the following cases show

CASE 1

A man, aged 21, was admitted to a surgical ward on Jan 21, 1949, with twelve hours' history of abdominal pain and vomiting He said he had had rheumatic heart disease since the age of 14, and was receiving digitalis, physical examination showed the presence of mitral stenosis with auricular fibrillation Mesenteric embolism was diagnosed and was confirmed at operation, but the collateral circulation seeming adequate, no resection was done After the operation the patient showed signs of overdosing with digitalis, so this drug was withheld The abdominal wound became infected, and on Feb 3, 1949, a secondary skin suture was done

On Feb 9, 1949, the patient began to have evening pyrexia up to 100 2°F Examination showed œdema of both legs, crepitations at the bases of both lungs, and probably an effusion at the base of the right lung There were no embolic phenomena, and blood cultures were sterile Small doses of digitalis were started again

On Feb 21, 1949, the patient was transferred to a medical ward because his cardiac failure was increasing and because it was thought that his pyrexia could not be due to the infected abdominal wound alone

Examination showed his jugular venous pressure raised to the angle of the jaw, bilateral œdema of the ankle but no sacral œdema, a right sided pleural effusion, the liver palpable three finger breadths below the right costal margin, and a moderate degree of ascites There were no embolic phenomena A swab from the wound yielded *Staph aureus* insensitive to penicillin, blood cultures were sterile, and a differential, white cell count was normal The patient's temperature began to settle during the next week

On March 4, 1949, injections of 'Neptal' were started (fig 1), 1 ml intramuscularly every day at about 9 A M A fairly good diuresis was produced

On March 12, 1949, the eighth day after the start of the daily injections, the patient had shivering and bouts of coughing at 11 30 A M —i e, about three hours after the injection His temperature rose to 100°F He began to perspire at 3 P M, and his temperature quickly returned to normal On March 13, 1949, exactly the same sequence of events recurred, except that in addition to the coughing and shivering the patient became much cyanosed and his extremities were very cold His temperature rose to 103°F, in the afternoon he perspired freely, and his temperature fell during the late evening The same thing happened on March 14, when his temperature rose to 104°F, and on March 15 when his temperature rose to 105°F The neptal was still being given every morning There were no changes in the physical signs in the cardiovascular system or the abdomen No embolic phenomena were observed, the spleen was impalpable, there was no clubbing, blood cultures were sterile, and a differenti white cell count and radiography of the chest revealed nothin abnormal

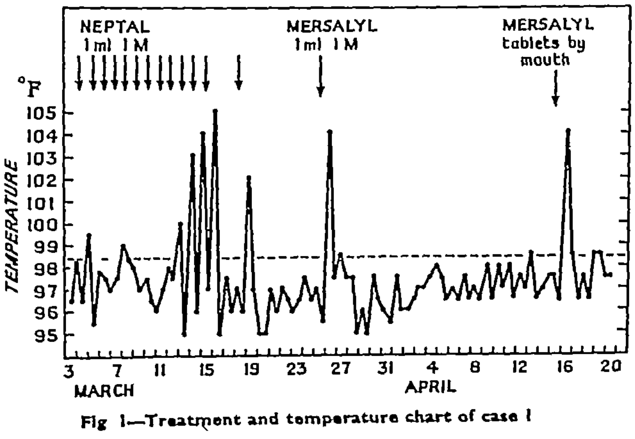

Fig 1—Treatment and temperature chart of case 1

On March 16, no neptal was given and the patient remaine afebrile throughout the day

On March 18 the patient was given neptal 1 ml. and had further rigor and his temperature rose to 103°F

On March 25 the patient was given an injection of mersaly 1 ml and had a rigor exactly similar to the ones apparentl provoked by neptal He still had the signs of cardiac failur with a raised venous pressure, peripheral œdema, a palpabl liver, and ascites

On March 29 at 3 P M, 0 1 ml of 1 84% neptal was injecte intradermally into the left forearm At 6 P M there was circular area of slight œdema 1 cm in diameter and erythem 3 cm in diameter There was also extremely well marke lymphangitis running up the medial aspect of the arm the axillary lymph glands were neither palpable nor tender A similar injection given to another patient as a contro produced an area of erythema 1 cm in diameter with no lymphangitis

It was thought that possibly the effects might have been due to the theophylline in the neptal, but no sensitivity was demonstrated when 'Cardophylin' was given intravenously or intradermally

On April 15, 1949, it was decided to try mercurial diuretics by mouth, and two tablets of mersalyl, each containing 0 08 g of mersalyl and 0 04 g of theophylline, were given. These produced cyanosis, coughing, and a rigor, and the patient's temperature rose to 104°F

The patient was given methyl thiouracil and digitalis, and with rest his cardiac failure improved sufficiently to warrant his being discharged to a convalescent home

CASE 2

An Irish labourer, aged 73, was admitted to hospital complaining of breathlessness on exertion, swelling of the legs for six months, and an irritative rash for about a month For two months he had been taking digitalis pills On examination he had congestive cardiac failure due to ischæmic heart-disease with auricular fibrillation and gross cardiac enlargement His rash was a patchy erythema

Treatment consisted of rest in bed, a low salt diet, and, from his fourth day in hospital, a daily intramuscular injection of neptal 1 ml His rash was successfully treated with 'Antistin' He lost two stone in weight in the first seventeen days and was much improved

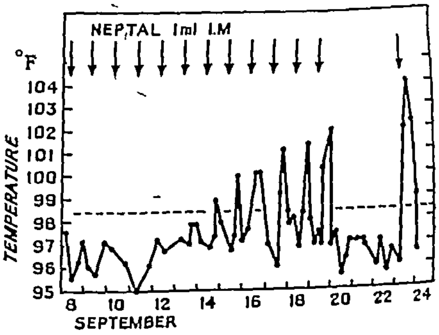

Fig 2—Treatment and temperature chart of case 2.

In the afternoon of the seventh day of his daily injections of neptal his temperature rose to 99°F, and on the next two afternoons it rose to 100° and 100 2°F, it was down to normal in the evenings (fig 2) The fever was associated with malaise and skin irritation

The patient was found to have a small pleural effusion, and it was thought that he might be developing an empyema He was treated with penicillin, in spite of which his temperature rose to 102°F, with a rigor, in the afternoon after his twelfth morning dose of neptal It was thought that, since the fever was so similar to that in case 1, it might also be due to neptal, so the injections were stopped The temperature remained normal in the next three days

To find out if the pyrexia was due to the diuretic, the patient was given 1 ml of mersalyl intramuscularly Five hours later his temperature rose to 104°F with the most severe rigor that he had had, much cyanosis, and skin irritation

To ascertain his sensitivity to neptal, an intradermal injection of 0 1 ml of a 0 46% solution of neptal was given which caused a patch of erythema 2 in in diameter in a control a similar injection caused a patch $^1/_2$ in in diameter To exclude the theophylline as being the cause of the

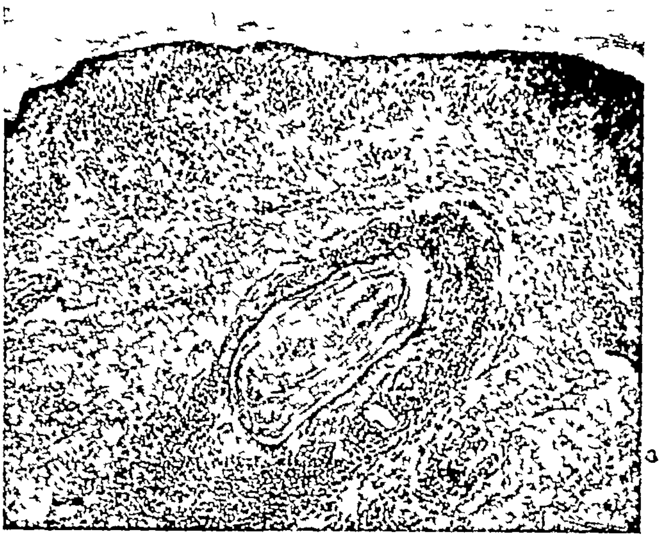

Fig 2—Epidermis affected by lichen striatus and showing irregular acanthosis, œdema, invasion by cells infiltration of papillæ, and perivascular and perifollicular reaction

cell thick The prickle cell layer showed an irregular acanthosis (fig 2) There was broadening of the rete pegs, with lateral fusion The basal cell layer was broken in places, especially in relation to the papillæ which were most infiltrated The prickle cell layer showed both intercellular and intracellular œdema (fig 3) This was most marked in the lower half of the epidermis and especially in relation to the papillary infiltration In these areas also the epidermis was infiltrated by the cells through the papillæ Patchy pigmentation was present There was some thinning of the epidermis in this region where the papillary infiltrate was very marked

Dermis—A considerable amount of cellular reaction was present and was mainly perivascular Lymphocytes and histiocytes were seen, together with melanophores No polymorphs or eosinophils were noted The cellular infiltrate was most marked in the papillæ and in the superficial part of the dermis but could be seen at deeper levels The capillaries were congested, and there was some œdema of the papillæ A hair follicle in the sections examined was surrounded by a heavy pleiomorphic infiltrate The outer sheaths of the hair follicle showed much intracellular œdema, and there was some vagueness in the line of demarcation between epidermal cells and infiltrate The collagen appeared unchanged The sweat-glands appeared normal, as did the sebaceous glands A nerve was seen in the section and appeared normal, but was associated with cellular infiltration, thus showing the depth to which the infiltration penetrated

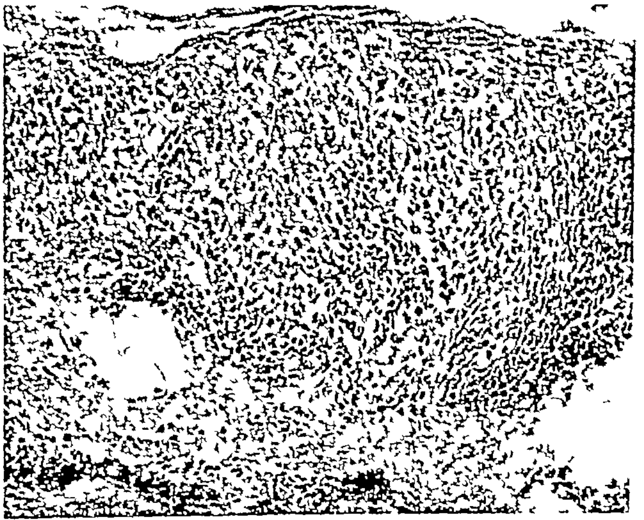

Fig 3—Epidermis affected by lichen striatus and showing intercellular and intracellular œdema of epidermis and cellular infiltration of epidermis and papillæ.

Elastic Tissue—Special stains showed that the elastic tissue of the corium was absent or much diminished in the papillæ, where there were areas of infiltration. Elsewhere the elastic tissue appeared normal

DISCUSSION

Lichen striatus has a distinct clinical picture with definite clinical and histological characteristics According to Senear and Caro (1941) the most striking feature is the course there is a sudden onset, followed by a rapid extension to form a linear band The lesions disappear in a few weeks or several months, either spontaneously or after the application of bland medicaments The eruption consists of lichenoid papules which primarily are small and discrete They may be flattened, glistening, and angular, but the angularity is produced by the normal markings of the skin The papules are not those of lichen planus, there is no umbilication or Wickham's striæ They coalesce to form an erythematosquamous dermatitis The bands, which may be homogeneous, consist of narrow parallel streaks, may be continuous or interrupted, and vary in length and width No preceding history of injury, local pressure, or contact with external irritants has been noted, and subsequent involution takes place without atrophy The condition is relatively asymptomatic

Senear and Caro (1941) described 10 cases in each of which there was a linear lichenoid papular eruption. With one exception this eruption involved the arms and was unilateral Of the patients, 7 were children In all instances the onset was sudden, the extension to form lichenoid bands rapid, and the eruption of short duration and self limited As a rule the disease was asymptomatic The eruption was composed of primary small lichenoid papules which often coalesced to form patches of lichenified dermatitis

Lewis (1942) reported a similar eruption on the left arm of a girl aged 13 The eruption consisted of lichenified discrete confluent scaly lesions grouped in a line Lichen planus was considered, but no typical papules were seen, and there were no buccal lesions Schmidt (1942) reported a case on the left arm of a five year old negro child Netherton (1944) reported a case in a woman of 44 with a five weeks' history, the eruption this time occurring on the right leg and extending from the right buttock downwards over the posterior surface of the thigh, calf of the leg, and forwards to involve the whole lateral surface of the right foot There was some itching Rothman (1946) reported a case in a child aged sixteen months, the eruption being along the line of the sciatic nerve Pinkus (1948) reported a case associated with lichen planus, the diagnosis was established with the help of the biopsy, and, whereas subsequently the lesions of lichen striatus disappeared, those of lichen planus persisted and recurred

Ætiology

Little is known about the ætiology of this condition, but Senear and Caro (1941) tried to explain the linear distribution by the concept of the existence in the skin of zones of increased irritability (fragile zones), which were determined congenitally by various factors In the case reported here the condition was preceded by rubella

Differential Diagnosis

The four conditions to be considered are linear psoriasis, linear lichen planus, linear nævus, and lichen striatus

It is characteristic of lichen striatus that the lesions are self limited and disappear spontaneously in a few weeks or months The other conditions usually display typical morphology, clinical characteristics, and histology, but the differentiation from lichen planus may be in table II There is no significant difference in the effectiveness of the two vaccines (level of significance P = 30% approx) It is important to note also that no allowance was made in the preparation of the Ty2 suspension for the added advantage of the A, B, and C components of the Lister vaccine

Finally, the sera from each group of rabbits immunised in the present series of experiments were pooled and filtered Passive protection tests in mice were carried out, using as controls sera prepared in 1939 against acetone dried suspensions of Ty2 and T6S In addition, we included a sample of the "provisional standard antityphoid serum" described by Felix (1938) and held at the Department of Biological Standards, National Institute for Medical Research Table III summarises the results of one passive protection test in mice The mucin technique was used in this experiment (Henderson 1939) The results show clearly that the protective value of the various sera are fully in accord with their agglutinin titres, and there is no suggestion of alteration in the efficiency of the antibody produced against the long stored antigen preparations

COMMENT

These simple experiments are of interest not only from the historical point of view, but also because they may provide a basis for research on the stability of typhoid and perhaps other vaccines It may prove that the acetone method of drying is not the most suitable Nevertheless, the evidence is that some form of dried vaccine is worthy of trial

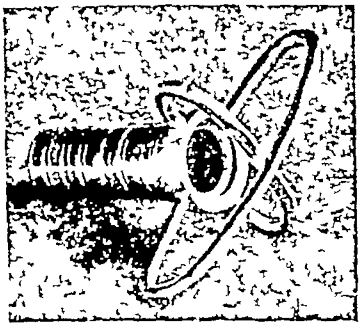
New Inventions

SAFETY ENDOTRACHEAL CONNECTION

THE under-mask method of endotracheal anæsthesia is probably the simplest technique and has a wide range of usefulness There must however be some arrangement to prevent the tube from slipping down the trachea, and to ensure that the open end of the endotracheal airway is not obstructed when in position under the mask The devices now used include a safety pin, one of the standard endotracheal connections, and the flange described by Gordon [1] All these are effective in preventing the tube slipping downwards but they do not guarantee a patent orifice A partial obstruction is commonly caused by the open end of the tube or its connection abutting against the inside of the mask.



I have recently been using the safety endotracheal connection shown in the figure, and have found the wire frame entirely successful in keeping the orifice free

The connection was made for me by the Medical and Industrial Equipment Co Ltd , of 12, New Cavendish Street, London, W 1

Reviews of Books

Psychological Factors of Peace and War

Editor Prof T H PEAR London Hutchinson 1950 Pp 262 16*s*

THIS is a book of outstanding importance, even though it contains little that is new to psychologists The scientific and medical professions have been slow to apply the findings of social science to their own thinking Not unnaturally they tend to continue to accept the face-value view of political processes which is accepted by the majority of their fellow citizens In this book Professor Pear has collected a series of essays on the socio-psychological, psychopathological, and demographic forces which produce international tension or operate in war time The underlying assumptions of the book are revolutionary, and despite its defects it marks a movement in scientific thought which may well have extensive repercussions on the attitude of scientists to the society in which they work Dr H J Eysenck's essay on war and aggressiveness, Prof J C Flugel on aspects of integration, and Dr H V Dicks on the German character, would be hard to better, and the essays achieve a level of objectivity which is a major feat in itself

In this book we see the translation into terms of practical political psychopathology of the pioneer work of Ruth Benedict, Lasswell, and many others It represents a tendency which no informed scientist can afford to ignore

Cancer Where We Stand

SIDNEY RUSS, O B E , D SC F INST.P , professor emeritus, University of London With a foreword by Lord HORDER London Oxford University Press 1950 Pp 192 10*s* 6*d*

MOST doctors would agree with Lord Horder's view, set out in a foreword to this book, that cancer is decidedly a subject which should be presented to lay readers , and in many ways Professor Russ is the right man to do it He explains the principles of modern X-ray and radium treatment clearly, and tells the history of their discovery with warm enthusiasm Other aspects of research are dealt with less fully, which may disappoint some readers Rightly or wrongly the layman believes that discovery of the cause could not but hasten discovery of a cure , and he likes to know how we are getting on

To show how much our present methods of treatment can accomplish, especially with the early case, Professor Russ publishes several tables showing 5 year survival figures To doctors these will appear encouraging enough, but laymen are less used to the cold blooded study of statistics They will notice, for example, that of 6380 patients treated by radiation only 2295 were alive five years , and this will leave them little heart to notice that of the 1727 early cases in this series no less than 1181 were alive five years later The same information could probably have been given more tellingly in the text

Nevertheless Professor Russ has put a good deal of information together on a subject of universal importance to mankind, and his book is welcome

Bacterial Toxins

W E VAN HEYNINGEN, M A M SC PH D , senior research officer, Sir William Dunn School of Pathology, Oxford Oxford Blackwell Scientific Publications 1950 Pp 133 15*s*

FOR some time past those interested in the biochemical activities of bacteria have spoken among themselves a language often barely intelligible to their colleagues It is therefore a pleasant task to call attention to a book, at once authoritative and readable, on bacterial toxins and their chemistry which should be easily understood by the workaday bacteriologist A subject to which chemists, pharmacologists, and pathologists have all made contributions in a great variety of journals is especially suited to publication in monograph Dr van Heyningen has himself made valuable additions to our knowledge, and his book succeeds in being more than a compilation. In particular he has abandoned the

PRESERVATION OF TYPHOID VACCINE

D W HENDERSON
D Sc, Ph D

S PEACOCK J RICHLEY

From the Microbiological Research Department, Porton, Wilts

THE storage of vaccines in liquid suspension is often unsatisfactory owing to serious loss in immunogenic value The loss is greatest if the materials have to be stored, transported, and used in warm climates In recent discussion on this subject we were reminded of materials one of us (D W H) had prepared in 1939 at the Lister Institute, Elstree There was reason to believe that they might still be in existence, and eventually they were unearthed Their history of "rough usage" could hardly have been more severe For some time they had been in a laboratory at Elstree (not to be described as cool in summer), then they were in a cellar for several years, thereafter they were "lost", and eventually they were found in a store which in summer weather gets well into the 80s One of us (S P) around 1948 was mindful of them and they were placed in a refrigerator It was here they were located a few months ago

TABLE II—ACTIVE PROTECTION TEST IN MICE

Antigen			Test dose (Ty2 intraperitoneally in 0 5 ml Ringer solution)	Mice		
Type	Doses (subcut)	Days between doses		Tested	Died	% survival
Acetone dried Ty2 (stored ten years)	(*a*) 2 × 10⁹* (*b*) 4 × 10⁹*	10	2 × 10⁸	60	8	86 7

Control mice			2 × 10⁸ 1 × 10⁸ 5 × 10⁷	20 20 20	20 18 12	0 10 40

Mice challenged 20 days after second dose of vaccine All animals from one stock Weight at commencement 18–20 g average weight at time of challenge about 28 g (0 5% non specific deaths during course of immunisation)

* Dose estimated on basis of opacity

† The preparation was stated to contain (per ml) 1000 million *S typhi* and 500 million each of *S paratyphi* A B, and C

Among them were acetone dried suspensions of *Salmonella typhi*, including the classical strains Ty2 and "O" 901, as well as a sample of the "pure" Vi strain T6S (Felix and Petrie 1938) The method for their preparation was as described by Henderson and Morgan (1938), and they were in 1 oz McCartney screw capped bottles with no special sealing By good fortune the preparation of the Ty2 strain had been used for the immunisation of rabbits (and horses) in 1939, and on close search some of the original rabbit immune serum was also located We decided, therefore, to examine the properties of some of these long stored antigens

Samples of each were re suspended in water, and groups of rabbits were injected intravenously, using the dose and time interval between doses that had been standard practice a decade earlier (Henderson 1939) The response was exactly as would be expected from using freshly prepared suspensions Table I shows the Vi and "O" agglutinin response of the rabbits to the Ty2 suspension, and includes for comparison an original pooled rabbit immune serum prepared in 1939 from the same material

TABLE III—PASSIVE PROTECTION TEST IN MICE

Rabbit serum				Challenge dose (Ty2)	Intravenous dose serum (ml)	Mice	
Antigen used for immunisation		Agglutinin titre					
Type	Age	Vi (T6S)	O ('O" 901)			Tested	Survived
Vi + O	10 yrs	1/600	1/10,000	5 × 10⁴	0 005 0 002 0 001 0 0005	10 10 10 10	10 8 9 4
(Ty2)	1 month	1/1000	1/2000		0 002 0 001 0 0005 0 0002	10 10 10 10	10 10 8 7
Vi	10 yrs	1/600	1/100		0 005 0 002 0 001 0 0005	10 10 10 10	10 8 9 1
(T6S)	1 month	1/1000	1/200		0 002 0 001 0 0005 0 0002	10 10 10 10	10 9 8 5
Provisional standard antityphoid serum (Vi + O) horse serum, dried		1/400	1/20,000		0 005 0 002 0 001 0 0005	10 10 10 10	8 6 6 3

Mucin controls						10	10

This encouraging result led to an active immunisation test in mice, using the same Ty2 material After consultation with Dr Felix, F.R.S., we included a group of mice, using as vaccine for them a current TABC alcoholised preparation made according to his method at the Lister Institute, Elstree (Felix 1941) The technique used for the experiment was that of Felix and Pitt (1934) Interestingly enough, the Ty2 stock used for the preparation of the challenge dose had also been laid down as "dried" culture in 1939, the technique used being that then in common use by the National Collection of Type Cultures The results are summarised

Folinic Acid: the “Citrovorum Factor”

The discovery that folic acid, an essential growth factor for *Lactobacillus casei*, was also needed for the proper maintenance of erythropoiesis and granulopoiesis in rats and pigs, and that in man it would cause the pathological megaloblastic erythropoiesis to return to normoblastic, revealed a hitherto unsuspected link between bacterial growth factors and factors of hæmatological importance. This link has been fully exploited both in the search for new factors and in devising methods for the microbiological assay of known hæmopoietic factors, such as vitamin B_{12}. The latter is a growth factor for another member of the lactobacillus family. The latest growth factor that promises to be of hæmatological interest is, however, necessary for quite a different organism—*Leuconostoc citrovorum*.

Sauberlich and Baumann[1] proposed to utilise *Leuconostoc citrovorum* for the microbiological assay of alanine. They were surprised to find that for satisfactory growth a factor had to be added to the medium that was not present in the usual “vitamin-B complex.” The best source of this growth factor was found to be the refined liver extracts prepared for treating pernicious anæmia. These refined extracts usually contain little folic acid, and tests with folic acid showed that, though it would assist the growth of *L. citrovorum*, the growth was not so good and the growth curve different. Later these workers[2] succeeded in preparing a concentrate of this “citrovorum factor” that was much more active, weight for weight, than folic acid. But it soon became clear that the citrovorum factor (C.F.) was closely related to folic acid. Sauberlich[3] had observed that rats fed on a diet deficient in folic acid excreted little C.F. in the urine; when folic acid was added to the diet there was a large increase of C.F. excretion. In man, too, administration of folic acid caused an increased excretion of C.F. in the urine. Sauberlich[4] further showed that aminopterin, a folic-acid antagonist, would inhibit the growth of *L. citrovorum*, and that C.F. would overcome this inhibition.

Nichol and Welch[5] provided more evidence. They found that when rats were fed on a diet deficient in folic acid, and had reached the stage of wasting with severe diarrhœa, their livers contained about twenty times *less* C.F. than a normal rat liver. When they incubated liver slices with folic acid, the C.F. content rose to the same high level with livers from both deficient and normal rats, the increase being much greater in the livers from animals on the diet deficient in folic acid. Ascorbic acid evidently played some part in this reaction, for it could double the C.F. content of incubated liver slices from either deficient or normal rats, and the greatest increase of C.F. content was obtained when the slices were incubated with folic acid and ascorbic acid together. Nichol and Welch therefore suggested that some at least of the added folic acid is converted enzymatically to citrovorum factor, and that ascorbic acid aids the conversion. Meanwhile, Bond, Bardos, Shive, and their collaborators at the University of Texas had been examining substances that they found to be effective in countering the action of folic acid antagonists, and they had discovered one that was considerably more effective than folic acid itself in neutralising the inhibiting action of methylfolic acid; they named this substance “folinic acid.”[6] They showed that folinic acid would support the growth of *Lactobacillus casei* in the absence of folic acid, and that it would act as a growth factor for *Leuconostoc citrovorum* in the same way as Sauberlich and Baumann's citrovorum factor. Later they reported[7] that by converting folic acid to formylfolic acid and then reducing the formylfolic acid in the presence of ascorbic acid they had produced a reaction mixture that was a million times more active, weight for weight, than folic acid in stimulating the growth of *L. citrovorum*. They were not sure whether this preparation was a single substance or a mixture, but they suggested that folinic acid contains a modified pteridine ring attached to the same groupings that are found in folic acid.

There seems to be little doubt that citrovorum factor and folinic acid, if not actually identical, are very closely related. Their relation to folic acid naturally suggests that they may have hæmatological actions. May, Sundberg, and Schaar[8] used crude folinic acid for the treatment of a megaloblastic type of anæmia produced in monkeys by dietary deficiency; the animals were also scorbutic. A dose of 50 *micrograms* of folinic acid caused a prompt response; the megaloblast-like cells disappeared from the marrow within 48 hours and the marrow was more or less normal within 10 days; there was a convincing increase of reticulocytes, red cells, and hæmoglobin. To get a similar effect with folic acid, a dose of 15 *milligrammes* had to be used. It is interesting to note that ascorbic acid did not have to be added to the diet for folinic acid to exert its action. Clinically, Schoenbach, Greenspan, and Colsky[9] gave synthetic citrovorum factor, presumably prepared from folic acid, to two patients who were receiving large doses of folic-acid antagonists for the treatment of malignant disease. One had received 10 mg. of ‘Amethopterin’ daily for 18 days and had developed a large ulcer on his hard palate. Citrovorum factor, 40 million units daily intramuscularly, was now given and the amethopterin continued. The ulcer healed on the 5th day, and new ulcers appeared when the citrovorum factor was stopped. The other patient was receiving 2 mg. daily of ‘Aminopterin’ and had developed stomatitis and ulceration of the mouth and palate; folic acid, up to 75 mg. daily, failed to heal the ulcers while the aminopterin was continued, and 20 million units of C.F. also failed; but when the dose was doubled the ulcers healed in 5 days.

It is clear then that citrovorum factor, or folinic acid, is yet another factor of much interest to hæmatologists. Reports on its action in human megaloblastic anæmias should soon be to hand, and we may speculate capillaries before the secondary results of their obliteration are well established. The main effect of obstruction in the pulmonary circulation is to increase the load on the right ventricle, so any chronic obstruction leads typically to pulmonary hypertension and hypertrophy of the right ventricle, which may or may not end in right-sided heart-failure. The term "cor pulmonale" is applied when some pulmonary disease directly or indirectly produces right ventricular strain, for various extra-pulmonary diseases can cause identical circulatory changes, and both groups will raise the blood-pressure in the pulmonary circulation. **GELFAND**[1] classifies the main causes of chronic pulmonary hypertension as follows:

1. *Cardiac group*.—Left-sided heart-failure from systemic hypertension, coronary sclerosis, or mitral stenosis—the condition lately discussed by **BAYLISS** et al.[2] in these columns. Congenital defects.

2. *Pulmonary group*.—Changes in the thoracic cage, such as kyphoscoliosis and those following thoracoplasty. Vascular changes, including arteritis and external pressure obstructing the pulmonary artery, and endarteritis obliterans of the pulmonary arterioles (Ayerza's disease). Changes in the lung parenchyma—either primary emphysema with or without fibrosis, or emphysema and fibrosis secondary to such chronic lung diseases as asthma, phthisis, pneumoconiosis, and bronchiectasis.

Why do some cases of long-standing asthma with emphysema develop cor pulmonale whereas others do not? This is one of the many questions being tackled by research-workers from occupational, constitutional, endocrine, and neurological standpoints. Modern techniques of investigation, and catheter studies in particular, by confirming the existence of pulmonary hypertension and making it measurable, are now focusing more and more attention on this condition. Clinically, as Dr. **EVAN BEDFORD** pointed out at the Royal Society of Medicine on Feb. 27, it can be recognised by well-defined physical signs—a diffuse apex beat, triple rhythm, a systolic murmur, and a loud pulmonary second sound, followed sometimes by the soft diastolic Graham Steell murmur in the pulmonary area. Some of his cases had hypercyanotic angina. In chronic asthmatics the development of cor pulmonale may be hard to detect, but **GELFAND** has adopted these criteria: (1) asthma and emphysema of at least 5 years' duration with no other heart disease; (2) an increase in the existing dyspnœa and cyanosis; (3) orthopnœa in a patient who has hitherto breathed better lying flat; (4) raised pressure in the pulmonary circuit (deduced or measured by catheter); (5) X-ray evidence of cardiac enlargement; and (6) electrocardiographic signs of right ventricular hypertrophy. Radiologically the pulmonary artery and its main branches are prominent; right ventricular enlargement makes the cardiac apex look abnormally square, and fullness of the right auricle produces some enlargement to the right. Usually both the heart rhythm and the systemic blood-pressure are normal.

When the heart-failure is secondary to chronic lung disease, such as bronchitis and emphysema, the prognosis is bad. Treatment is directed not at the heart but at the lungs, for these patients die a pulmonary death of anoxia, usually from a terminal bronchopneumonia. At the Royal Society of Medicine Dr. J. P. D. **MOUNSEY** demonstrated that when such patients get a pulmonary reinfection there is always a rise in their pulmonary arterial and venous pressures and a fall in their vital capacity. Prof. E. P. **SHARPEY SCHAFER** sets great store on the oxygen tent, but in some cases, he said, it causes a rise in cerebrospinal fluid pressure, which may explain the mental confusion that sometimes occurs in spite of the relief of cyanosis. He strongly favours determinations of arterial oxygen saturation for estimating cardiac function and as a guide to treatment. In some emphysematous subjects, well enough to sit up in bed and read a newspaper, he has been surprised to find arterial oxygen saturation values below 40%. This suggests that such cases have an effective compensatory adaptive mechanism, which may prove to be the high pulmonary arterial pressure. He has tried to reduce the cardiac output therapeutically with large doses of thiouracil (up to 2 g. daily) with a beneficial raising of oxygen saturation. However, the bigger fall in cardiac output which occurs in the terminal stages of pulmonary heart-failure is accompanied by a compensatory peripheral vascular constriction, and the heart then reaches a stage of fixed output from which recovery is impossible.

Uniform histological changes in the pulmonary capillaries in pulmonary heart-disease were regarded by Dr. **WILLIAM EVANS** as responsible for the variability of its clinical course. He showed examples of pulmonary arteriolar medial endarteritis fibrosa and correlated its degree with the clinical findings in different conditions. For example, in a case of patent ductus arteriosus, electrocardiographic evidence of right ventricular predominance was in his opinion proof that endarteritis was present, causing pulmonary hypertension by involving the lesser branches. In some instances the Gibson murmur might even be absent when a high pulmonary arterial pressure obliterated the fistula effect, and these cases could be mistaken for atrial septal defect. Pulmonary heart-failure of whatever cause, he said, is usually related to pulmonary endarteritis, and this can be demonstrated post mortem. By injecting the pulmonary arterial tree with a radiopaque substance he had obtained pictures which showed a pruning effect of the terminal branches when endarteritis was present. With characteristic simile he described how the lungs differed in pulmonary heart-disease and in pure emphysema "as a denuded shrub in autumn differs from a leafy bush in spring." Though he argued that this pathological change is always the primary cause of pulmonary hypertension, analogy with the histological findings in systemic hypertension suggests that it may represent the end result. Much still remains to be explained before Dr. **EVANS**'s ingenious hypothesis is proved.

Recently interest has again turned to the bronchial vascular system[3] and future work may disclose further evidence of the function of a bronchopulmonary precapillary anastomosis, playing an important part in pulmonary heart-disease by redistributing the flow of blood within the lungs.

Sweden has staffing difficulties like the rest of us Nurses are scarce, but, on the other hand, if they take up the profession they seem to stick to it wastage is said to be only 3% This may be partly because nearly all the trained staff live outside the hospital, and appreciate the opportunity, but it may also be because the Swedish nurse has a very interesting training, with experience of laboratory work and radiology When she is qualified, moreover, she is entrusted with important technical duties for example, blood-transfusions are almost everywhere given by nurses The British visitors were inclined to shake their heads over the time spent by Swedish nurses in the X ray department and the various laboratories, taking this into account, they thought 3 years and 5 months was not long enough to train a nurse Canadian experience, however, has shown that an intelligent girl can become proficient in nursing in 2 years are the Swedes perhaps right in using the remaining 17 months to stretch her mind? Evidently girls who are capable of managing responsible procedures, are entering the Swedish nursing service, and a wastage of only 3% from such a class of entrants means that the training has captured their enthusiasm We might well aim to do as much ourselves

CARDIAC ARREST UNDER ANÆSTHESIA

No more dramatic event takes place in an operating-theatre than cardiac arrest under general anæsthesia, for everything may hang on early recognition of this complication and on swift and decisive action The fact that full recovery is possible even after the heart has stopped for a considerable time is shown by a case studied by Turner[1] The patient was anæsthetised by thiopentone and cyclopropane, and after seven minutes' stoppage the heart was made to beat again by cardiac massage through a subcostal incision During the next twenty four hours it stopped beating four times and breathing stopped several times, but on the second day deepening coma was replaced by gradual return of consciousness, and by the tenth day the patient was fully orientated He had a permanent retrograde amnesia of twelve hours and a postoperative amnesia of about four days, and a year after the accident he had symptoms suggestive of a mild frontal lobe syndrome But after a further twelve months recovery seemed complete

Anderson and her colleagues[2] keep in the theatre a "cardiac resuscitation kit" consisting of 2 small retractors, 6 curved and 6 straight hæmostats, 2 toothed forceps, and 2 scalpels, together with a syringe containing 9 5 ml. of 1% procaine and 0 5 ml of 1 in 1000 adrenaline When warned of cardiac inhibition, the surgeon's first duty, if he is operating on the abdomen or chest, is to confirm that the great vessels are pulseless, and his next task is to reach the heart by whatever route seems best, not hesitating, if need be, to enter the left side of the chest through the fourth or fifth intercostal space[3] "All surgical residents early in their training should be shown at the autopsy table how best to approach the heart for massage through the chest and through the diaphragm" With the anæsthetist maintaining artificial respiration by intermittent compression of the breathing bag, the surgeon compresses the heart at a rate of 60–80 per minute (120 is the most efficient rate, but it is too tiring for a single surgeon) Further action, if spontaneous rhythm is not soon resumed, depends on whether the heart is found to be fibrillating or at a standstill. If fibrillation is found, and if the electrical apparatus for serial defibrillation is not at hand, 40–60 mg procaine in a 1% solution is injected intravenously This may restore normal rhythm or bring the heart to a standstill, in the latter event (and when the heart is found in the first place at a standstill) manual massage will often suffice to bring about normal rhythm, but the heart beat will be strengthened by injecting up to 0 5 ml. of 1 in 1000 adrenaline into a vein or into the right auricle or ventricle Anderson et al defend their combination of procaine and adrenaline in a single injection on the ground that when circulatory arrest develops it is rarely possible to be sure whether the cause is cardiac standstill or ventricular fibrillation

The mechanism of cardiac arrest under general anæsthesia has been studied by Johnstone,[4] who concludes that probably the anæsthetic stimulates sensory nerve endings in the lungs with resulting inhibition through the pulmo cardiac reflexes The arrhythmias to which the inhibition gives rise include sinus bradycardia, auriculoventricular nodal rhythm, partial and complete auriculoventricular block, ventricular standstill, and complete cardiac arrest He judges that before operation atropine gr $^1/_{100}$ intravenously probably protects against cardiac inhibition for about thirty minutes, and gr $^1/_{50}$ intramuscularly for ninety minutes, but special care to avoid high concentrations of anæsthetic vapours should be taken where vagal tone is increased (as with jaundice, simple sinus bradycardia, and peptic ulceration) Johnstone emphasises that simultaneous intravenous administration of atropine and neostigmine to anæsthetised patients is dangerous, for in combination they may precipitate fatal ventricular fibrillation, and the only way to eliminate this danger is to give minimal doses of curare, thereby eliminating the need for neostigmine Johnstone maintains that in cases of myocardial disease or where anæsthesia is protracted, electrocardiographic records should be taken during the operation

OUR ELDERS

VOLUNTARY and statutory bodies have formed many notable alliances in the cause of social welfare In the last few years their joint endeavours have made a remarkable difference to those old people whose lot has fallen to them in unpleasant places, and their projects have owed much, both in counsel and cash, to the National Corporation for the Care of Old People[5] In the past year the governors have had in mind the difficulties voluntary bodies nowadays meet in attempting to raise money, and have therefore increased the average amount of grants above the sums given in previous years, especially to homes for the infirm A condition is that the voluntary bodies applying for grants should apply to the appropriate local authority for help with the maintenance costs of individual residents, and nearly every authority approached has responded—without, moreover, attempting to make strict conditions Two county boroughs, only, have refused The governors point out that such refusals are shortsighted, for all the homes that can be provided are needed urgently, and an authority can only benefit by having a home provided and run by a responsible organisation If authorities would go even further and agree to pay the whole cost of maintaining old people in such homes, the voluntary bodies could, of course, do much more, but so far only a few authorities have agreed to this course.

Towards the end of the year the governors arranged that Mr Howell E James should visit the homes to which grants had been made, partly to see how the funds were being used but mainly to help in planning future policy Some homes have solved problems with which others are still wrestling, and the governors hope to pool such experience for the benefit of all One problem presented by the old is that they grow older, and

whether folinic, rather than folic, acid is the important factor in the treatment of these diseases, and whether folic acid really acts only when converted to folinic acid. It should not be hard to get the facts, but we hope that a sufficiency of reliable clinical tests will be assembled before any new theories about the ætiology of megaloblastic anæmias are proposed.

Annotations

SYMPTOMS OF PUBERTY

"JUVENILE delinquency is what the law says it is", and the law draws the line in different places in different countries. Dr Lucien Bovet, who quotes this saying in a new W.H.O. monograph,[1] notes that in many European countries a minor is a delinquent only if his behaviour is an offence to the whole population, whereas in parts of the United States he may be brought into court for a number of other things, including truancy from school, consistent disobedience to parents, consumption of alcohol, and smoking in public. In England a boy is legally incapable of sexual intercourse before the age of 14; and though he may have raped another child and caused her death, if he is less than 14 he must be declared "not guilty". A country with an efficient police force has a higher delinquency rate than a country where the police are slack; and in any country the social position and influence of the parents may decide whether a child is charged or not. Even the severity with which an offence is punished varies from one magistrate or judge to another. Indeed, our response to the whole idea of juvenile delinquency is illogical. We can never outgrow, it seems, our astonishment that those so young should be so bad; yet statistics make it quite clear that the peak age for crime is in the teens and early twenties. In other words, if criminal behaviour is ever to be expected, it is to be expected then, along with neurotic or schizoid episodes, erotic fantasies, physical ebullience, a taste for brilliant garments, and all the other signs of adolescent instability and stress.

Moral indignation is no more relevant to the aberrant conduct of the adolescent than it would be to the depression, hot flushes, and giddiness of the menopausal woman: both are expressions of hormonal disequilibrium of which the subject is only obscurely conscious. The social difficulty is that in the adolescent such expression may range from giggling inconsequence to seemingly wanton destructiveness or brutal outrage. What decides the form it takes? That is for research to discover, as Dr Bovet insists. Mr Joyce Carey, in *Charley is my Darling*, gives an intuitive answer as far as destructiveness goes. The need to boast, the need to make the boast good, the need to get excited and break things, are not forces the boy can reason about; they befall him, and so do the consequences. Probably no living adult has made the curious and difficult adjustment perfectly at every step; who, then, is qualified to advise the growing child? Dr Bovet's monograph is studded with reports of our ignorance, but he outlines the growing body of knowledge and opinion and directs attention to whatever is sure.

Treatment may vary—and indeed it should vary, if it is to be adapted to the needs of individual children—but the aim of even the most diverse methods is the same: to help the child to build up safe and stable relationships with the people round him, and to achieve that inner security on which are founded his own moral independence and that consideration for others which lies behind good social behaviour. In time we shall know better how to do this difficult thing.

SWEDISH HOSPITALS

SWEDEN, with its lakes and forests, clean air, and bracing climate, is a fine place for hospitals; and indeed it has some of the most up to date hospitals in the world. Nevertheless, the members of the International Hospital Federation[1] who made a study tour of Swedish hospitals last September were more taken with the older, smaller, more homely, hospitals than with the great Södersjukhus at Stockholm,[2] with its 9 floors, 40 wards, 50 lifts, and vast central kitchen, perched at the top of the main block and connected to its 11 branch kitchens by a 400 ft corridor, along which the staff dash to and fro on scooters. Scooters, indeed, are a good idea, and might well be introduced into some of our own long hutted hospitals (Stoke Mandeville, for instance). But the mere notion of anything so large as the Södersjukhus shocks our new British thrift, concerned as never before with the cost of upkeep. The expense of maintaining the great place is, in fact, already beginning to weigh heavily on the authorities of this hospital.

We have plenty to learn, however, from other aspects of the Swedish hospitals. They seem to pay more attention to the comfort of the patient and his relatives than is usual here. These hospitals are quieter than ours, for instance: walls and ceilings are made of sound absorbing material, and lift doors of wood with no clanging inner gates; trolleys are often electric and are all well made and easy to move; doors are fitted with door checks, and many of them are designed to push open so that noisy handles are unnecessary. Relatives are received in a large and pleasant entrance hall which usually contains a florist's shop, a tobacco and news paper stall, a cafeteria, and sometimes a post office, and a hairdressing salon for the use of ambulant patients. There is nearly always an information bureau as well, and a large model of the hospital on which a visitor can learn his way about. The beds, it is true, were thought to fall short of British models. They measure 2 ft. 6 in. across, and have their bottom legs set back some way from the foot, which gives them rather a makeshift look. Actually they are rather ingenious, for they are fitted with a wheeling device, and when the foot is lifted they can be pushed easily about like a wheelbarrow. Screens are not used in the wards, since treatments, dressings, and blanket baths are given in a separate annexe and patients are usually wheeled to the water closet either in their beds or in a lavatory chair. This must reduce greatly the traffic in bedpans, though these are of course provided. The pans are all made of stainless steel, and are well maintained, though the cleaning equipment is not of that latest type which cleans and sterilises. They are washed in a deep metal sink, usually in cold water, sometimes under pressure; but they are only sterilised in maternity and gynæcological wards. The pans are numbered, however, and each patient retains his own throughout his stay in hospital.

The medical equipment is of a very high standard indeed, and extremely lavish and well cared for. Theatres in the newer hospitals are spacious and well planned, and many operations are done by daylight—another advantage of clean bright air. In the wards lights are conveniently placed over the beds, and are often fitted with a revolving shutter which allows the patient to adjust the amount of light given out. The night light is never overhead, but usually placed in a recess in the wall, near the door, about a foot from the floor. In one hospital the night light was sunk flush in the centre of the floor of the ward, which must give a specially restful effect.

Sweden has staffing difficulties like the rest of us Nurses are scarce, but, on the other hand, if they take up the profession they seem to stick to it wastage is said to be only 3% This may be partly because nearly all the trained staff live outside the hospital, and appreciate the opportunity, but it may also be because the Swedish nurse has a very interesting training, with experience of laboratory work and radiology When she is qualified, moreover, she is entrusted with important technical duties for example, blood transfusions are almost everywhere given by nurses The British visitors were inclined to shake their heads over the time spent by Swedish nurses in the X ray department and the various laboratories, taking this into account, they thought 3 years and 5 months was not long enough to train a nurse Canadian experience, however, has shown that an intelligent girl can become proficient in nursing in 2 years are the Swedes perhaps right in using the remaining 17 months to stretch her mind? Evidently girls who are capable of managing responsible procedures, are entering the Swedish nursing service, and a wastage of only 3% from such a class of entrants means that the training has captured their enthusiasm We might well aim to do as much ourselves

CARDIAC ARREST UNDER ANÆSTHESIA

No more dramatic event takes place in an operating-theatre than cardiac arrest under general anæsthesia, for everything may hang on early recognition of this complication and on swift and decisive action The fact that full recovery is possible even after the heart has stopped for a considerable time is shown by a case studied by Turner[1] The patient was anæsthetised by thiopentone and cyclopropane, and after seven minutes' stoppage the heart was made to beat again by cardiac massage through a subcostal incision During the next twenty four hours it stopped beating four times and breathing stopped several times, but on the second day deepening coma was replaced by gradual return of consciousness, and by the tenth day the patient was fully orientated He had a permanent retrograde amnesia of twelve hours and a postoperative amnesia of about four days, and a year after the accident he had symptoms suggestive of a mild frontal lobe syndrome But after a further twelve months recovery seemed complete

Anderson and her colleagues[2] keep in the theatre a "cardiac resuscitation kit" consisting of 2 small retractors, 6 curved and 6 straight hæmostats, 2 toothed forceps, and 2 scalpels, together with a syringe containing 9 5 ml. of 1% procaine and 0 5 ml of 1 in 1000 adrenaline When warned of cardiac inhibition, the surgeon's first duty, if he is operating on the abdomen or chest, is to confirm that the great vessels are pulseless, and his next task is to reach the heart by whatever route seems best, not hesitating, if need be, to enter the left side of the chest through the fourth or fifth intercostal space[3] "All surgical residents early in their training should be shown at the autopsy table how best to approach the heart for massage through the chest and through the diaphragm" With the anæsthetist maintaining artificial respiration by intermittent compression of the breathing bag, the surgeon compresses the heart at a rate of 60–80 per minute (120 is the most efficient rate, but it is too tiring for a single surgeon) Further action, if spontaneous rhythm is not soon resumed, depends on whether the heart is found to be fibrillating or at a standstill. If fibrillation is found, and if the electrical apparatus for serial defibrillation is not at hand, 40–60 mg procaine in a 1% solution is injected intravenously This may restore normal rhythm or bring the heart to a standstill, in the latter event (and when the heart is found in the first place at a standstill) manual massage will often suffice to bring about normal rhythm, but the heart beat will be strengthened by injecting up to 0 5 ml of 1 in 1000 adrenaline into a vein or into the right auricle or ventricle Anderson et al defend their combination of procaine and adrenaline in a single injection on the ground that when circulatory arrest develops it is rarely possible to be sure whether the cause is cardiac standstill or ventricular fibrillation

The mechanism of cardiac arrest under general anæsthesia has been studied by Johnstone,[4] who concludes that probably the anæsthetic stimulates sensory nerve endings in the lungs with resulting inhibition through the pulmo cardiac reflexes The arrhythmias to which the inhibition gives rise include sinus bradycardia, auriculoventricular nodal rhythm, partial and complete auriculoventricular block, ventricular standstill, and complete cardiac arrest He judges that before operation atropine gr $^{1}/_{100}$ intravenously probably protects against cardiac inhibition for about thirty minutes, and gr $^{1}/_{50}$ intramuscularly for ninety minutes, but special care to avoid high concentrations of anæsthetic vapours should be taken where vagal tone is increased (as with jaundice, simple sinus bradycardia, and peptic ulceration) Johnstone emphasises that simultaneous intravenous administration of atropine and neostigmine to anæsthetised patients is dangerous, for in combination they may precipitate fatal ventricular fibrillation, and the only way to eliminate this danger is to give minimal doses of curare, thereby eliminating the need for neostigmine Johnstone maintains that in cases of myocardial disease or where anæsthesia is protracted, electrocardiographic records should be taken during the operation

OUR ELDERS

VOLUNTARY and statutory bodies have formed many notable alliances in the cause of social welfare In the last few years their joint endeavours have made a remarkable difference to those old people whose lot has fallen to them in unpleasant places, and their projects have owed much, both in counsel and cash, to the National Corporation for the Care of Old People[5] In the past year the governors have had in mind the difficulties voluntary bodies nowadays meet in attempting to raise money, and have therefore increased the average amount of grants above the sums given in previous years, especially to homes for the infirm A condition is that the voluntary bodies applying for grants should apply to the appropriate local authority for help with the maintenance costs of individual residents, and nearly every authority approached has responded—without, moreover, attempting to make strict conditions. Two county boroughs, only, have refused The governors point out that such refusals are shortsighted, for all the homes that can be provided are needed urgently, and an authority can only benefit by having a home provided and run by a responsible organisation If authorities would go even further and agree to pay the whole cost of maintaining old people in such homes, the voluntary bodies could, of course, do much more, but so far only a few authorities have agreed to this course.

Towards the end of the year the governors arranged that Mr Howell E James should visit the homes to which grants had been made, partly to see how the funds were being used but mainly to help in planning future policy Some homes have solved problems with which others are still wrestling, and the governors hope to pool such experience for the benefit of all One problem presented by the old is that they grow older, and some who were hale enough when admitted have later become infirm Most homes have been planned and staffed to take residents who are fit, and they cannot easily cope with illness One way of overcoming the difficulty is to appoint more staff this adds to the cost of maintenance, but the governors point out that there is a real need for enough staff to manage these inevitable episodes in the lives of the old It would of course be wrong for a home to keep any resident who needed hospital treatment, but then a hospital bed cannot always be found

[5] Third Annual Report for the year ended Sept 30 1950 Pp 26 The corporation s address is 33 Doughty Street London W C 1

As everyone now knows, many hospital beds are occupied by old people who could be sent out—at all events for a time—if they had somewhere suitable to go, and the governors have for some time been planning to pay the capital cost of rest-homes which would receive them, and so free beds for others Unfortunately there are administrative difficulties Sick old people come under the National Health Service, while those who need care and protection come under the local authorities, and the suggestion of the governors is that the maintenance costs of patients in the home—who would belong to both categories—should be shared between the hospitals and the local authorities in proportions to be agreed upon from time to time So far it has not proved possible to proceed on this basis However, the governors have at their disposal a large fund generously given by the people of South Africa, which they intend to spend on experimental work for old people They have therefore bought Warren House, at Stanmore, which they hope to run in conjunction with the West Middlesex Hospital, where Dr Marjory Warren has charge of the geriatric unit, as a rest home of the kind described This should show whether the administrative difficulties are insuperable or not Those who believe in the value of a fait accompli will be greatly astonished if they are

SOCIAL CONSEQUENCES OF PNEUMOCONIOSIS

BETWEEN January, 1931, and July, 1948, over 19,000 cases of pneumoconiosis were certified in South Wales Some 16,000 of these men are now living, and about a quarter of them are capable of useful work but cannot find it The problem is a residue of the Workmen's Compensation Act which, on certification, suspended men automatically from further mining Under the National Insurance (Industrial Injuries) Act, 1946, this no longer holds, and some men can and do continue to work in the pits The end of pneumoconiosis, however, is not yet to be, and for various reasons several thousand men with this disease are likely to be unemployed for some years to come The Medical Research Council's pneumoconiosis unit[1] are anxious that better provision should be made for them Provided it is not with "pick and shovel," the men with lesser disability can do a useful job of work, "and nothing else can prevent the mental and physical deterioration that so often accompany enforced idleness"—or ensure a reasonable standard of living

This M R C memorandum sets out clearly the main facts together with their statistical background from the Social Survey and elsewhere, and a dozen case histories bring the problem very much to life The authors make two recommendations (1) that suitable work be offered, and (2) that a regular medical follow up of certified men be instituted It is depressing to read how so many of the brave hopes of the Disabled Persons Employment Act, Remploy, the Grenfell factories, the reablement centres, and the Board of Trade's development scheme remain unfulfilled South Wales has more men unemployed than the rest of the country and more who are disabled Special measures are therefore necessary, and though on suitable light work men with lesser degrees of pneumoconiosis have no higher sickness and absenteeism rates than average, local private employers cannot be expected to carry the whole responsibility The follow up of certified men would provide specialised medical advice otherwise not available, and the results of the examinations would be used in an attempt to grade the men according to the type of employment for which they are fit, in this way more could be learnt about prognosis In the memorandum Hugh Jones and Fletcher give their preliminary ideas on possible methods of such an "aftercare" scheme, but more would have been welcome Could the scheme be joined, for instance, to that for the periodic examination of all South Wales coalminers which the unit is advocating?[2] Opinion, it is true, is divided about both the practicability and the advisability of this scheme,[3] and there has been far too little discussion of it.

The pneumoconiosis research unit is clearly taking full advantage of its great opportunity The South Wales coalfield has many problems,[4] and we look forward to further such reasoned and helpful studies The unit only discusses remedies which are "properly the responsibility of medical men", but this need not be unduly restricting, since for more than a century everything that affects the health of the people has been regarded as such a responsibility Wider opportunities will no doubt be found in the reablement centre for miners with pneumoconiosis which, the Minister of Health announced in Cardiff last week, is to be set up near the unit's headquarters at Llandough Hospital

SECOND THOUGHTS ON THE COLOMBO PLAN

JUDGING by reports in the press, the American reaction to the Colombo plan is uncertain and wavering If what we believe[5] to be a great and imaginative conception has not been received with the full sympathy that it merits, we must remember the recent American agreement to ship one million tons of wheat to India. It is difficult to appreciate the significance of this huge figure, and to picture the bulk of food involved. It would suffice to supply each of the 347 million inhabitants of India with 12 oz of cereal (the daily cereal ration in some parts of India) for between seven and eight days. The value of this to a people accustomed to awaiting with trepidation an uncertain harvest cannot be exaggerated In economic terms the cost is $100 million At individual level, each citizen of the U S A has contributed about 70 cents, and to pay the debt each citizen of India must provide rupees 1 annas 6 The thoughtful American may well wonder how this account can be settled, and hesitate before rushing into new and uncertain investments in South-east Asia

We can only reiterate that on public health grounds alone it is imperative to develop the latent wealth of South east Asia by schemes along the broad lines of the Colombo plan The financial difficulties are immense it would be folly to minimise them World economists have before them the great task of finding means of developing the backward parts of the world without impoverishing more fortunate areas at the same time Essentially it is a problem of credit, which means faith

W. R. HESS.

THE CONTROL OF THE AUTONOMIC NERVOUS SYSTEM BY THE HYPOTHALAMUS

D. A. McDONALD
M.A., B.M. Oxfd

SENIOR LECTURER IN PHYSIOLOGY, ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, LONDON

Professor Hess in Zürich has been studying the autonomic and central nervous systems for the past quarter-century and more. His method of stimulating the hypothalamus in a fully conscious and freely moving animal is of particular interest, for it forms the closest parallel that experimental physiology has made to clinical observation.[1] Yet current teaching of the functions of the hypothalamus is based almost entirely on American and British work. Even research publications have few references to Hess's results.

The reasons for this neglect of his writings, here and in America, are difficult to determine. Though the papers are mainly published in German, they have all appeared in easily accessible journals, and two summaries have been published recently—namely *Die funktionelle Organisation des vegetativen Nervensystems* (1948) and *Das Zwischenhirn: Syndrome, Lokalisationen, Funktionen* (1949).[2] These books summarise work on the nervous system for which he was awarded a half-share of the Nobel prize in 1949. A review of his contributions to present knowledge is, therefore, appropriate now. It is based on the two monographs named, and on personal observations.[3]

METHODS

Das Zwischenhirn covers the results of experiments on the diencephalon, the thalamus, subthalamus, hypothalamus, and adjacent regions. The animals used throughout are cats. They are stimulated by steel needle electrodes (about 0.25 mm. thick and insulated to within 1.0 mm. of the tip), which are placed in the brain, under nitrous-oxide anæsthesia at the beginning of the experiment. They are fastened by means of a rectangular frame screwed to the skull. This fixes their direction and each experiment is based on the study of stimulation of these fixed electrode positions. The placing is afterwards checked by a complete histological investigation of the brain in each case. Symbols of the type of response seen are then mapped on to diagrams of the diencephalon at the site where they were obtained and they may be seen in these monographs. One is reproduced below.

Stimulation is by direct current pulses. Although this is the standard method of stimulation nowadays, using electronic apparatus, Hess designed his own machine over 20 years ago as a result of studies of the optimal conditions of stimulating autonomic nerves. Destructive lesions can be made by coagulation at the tip of a given electrode with diathermy current (see Hess 1932).

It is the study of the unnarcotised animal which is the unique feature of Hess's work on the central nervous system. The advantages of eliminating the unknown factors of anæsthesia, and operative trauma, need hardly be stressed. Correspondingly, experimental recording of an untrammelled animal is difficult and interpretation of its complex behaviour with its idiosyncrasies, and individual peculiarities of character, raises its own special problems. Records, therefore, consist of detailed observations dictated throughout the experiment, together with cinematic recording of all significant findings. It is a truly biological way of studying animal behaviour, an approach that is too easily lost in the increasing technicalities of physiology. Bird-watching has been raised to quite a respectable branch of biology, but cat-watching has relatively few supporters. Professor Hess is undoubtedly the world's greatest cat-watcher. That is not to decry his wide range as an experimental scientist, for he made early fundamental contributions to the study of blood viscosity (between 1907 and 1920), and to the investigation of squint (Hess screen) (Hess 1911), in addition to the work under review. Perhaps it is the slightly unorthodox attitude of wishing to study the intact animal, instead of a refined "preparation" such as the isolated brain, or a single segment of spinal cord, that has led to his neglect by Anglo-American physiologists. Also, without seeing his experiments, or the films of them, it is difficult to appreciate them.

AUTONOMIC ACTIVITIES

The technical details summarised here are to be found in the third section of *Das Zwischenhirn*. The first part deals with the autonomic nervous (vegetative) effects seen in over 400 animals. In the anæsthetised animal a large number of experiments have been performed recording blood-pressure changes. A rise in pressure is regularly obtained from a wide region of the posterior hypothalamus. A fall was obtained from zones including the anterolateral hypothalamus, and parts of the subthalamus and anterior thalamus. In addition to the marked effect on blood-pressure there is usually an increase in heart-rate observed at the same points, while a slowing of the pulse is seen, on occasion, with a fall in pressure.

Respiration is also greatly modified by stimulating the diencephalon, both its amplitude and its rate and character. Increased respiratory activity is seen with stimulation in the lateral part of the posterior hypothalamus. Decrease of rate and amplitude results from stimulation of the area supraoptica and also from widespread points in the septum pellucidum, and laterally in the subthalamus and inferior thalamus. An increase of rate alone (paroxysmal tachypnœa) is seen in the anæsthetised cat with stimulation of the anterior superior part of the hypothalamus and the neighbouring regions.

Comparison with the unanæsthetised animal suggests that the tachypnœa is not due to interference with normal respiratory regulation but is, in fact, the same as panting and so a response to stimulation of the temperature-regulating mechanism. Without anæsthesia, however, the response is obtained from a much wider field. The analysis of such comparable responses in anæsthetised and unanæsthetised animals are obviously of great importance in assessing the significance of experiments on the central nervous system of narcotised animals.

Another autonomic activity noted in the hypothalamus is that controlling pupil size. Dilatation, with widening of the palpebral fissure, is obtained from the same zone as that causing a rise in blood-pressure. Pupillary narrowing is the response from a small region lateral to the supraoptic nuclei and also in the mid thalamus.

All these observations are of interest in so far as they confirm, or contrast with, the results of other workers using different techniques. Many medical men, however, may be more interested in the coördinated activity reactions that Hess has recorded as a response to stimulation in the intact cats. Sneezing is often caused by stimulating the septum pellucidum. Other effects functionally related are sniffing, licking movements, salivation, and vomiting In order that the biological significance of these functions may be assessed they must be considered in relation to the other effects occurring at the same time Thus, salivation occurs at virtually all points that produce panting, and in this case presumably is activated by the heat regulating mechanism In other places salivation accompanies licking and sniffing, and so, reasonably, is regarded as digestive in function Licking movements are of divers forms, from isolated or rhythmic licks to fully organised licking and chewing Rhythmic licking results from thalamic stimulation, whereas more fully developed mastication is localised in the septum pellucidum

---

[1] G. W. Harris at Cambridge has subsequently developed another technique for stimulation of the conscious animal.

[2] Both published by Benno Schwabe, Basle. Although the text is in German, all the numerous illustrations and charts are subtitled in English.

[3] I am grateful to the Leverhulme Foundation for a research grant that made possible a period of research in Professor Hess's laboratory in 1949.

Vomiting, although not commonly elicited, is divided into two types One is apparently like normal vomiting, and is obtained from the level of the corpora mammillaria but more laterally A second type, which is got from the ventral nucleus of the thalamus, is associated with "gagging" and choking, as though the vomiting was initiated by sensations in the back of the throat Rubbing at the mouth with a paw, "as though trying to remove a foreign body," and twitching of the nose occur as well, which, with the licking movements noted above, support the opinion that the cat is responding to sensory stimuli referred to these areas This provides a good example of the lines along which Hess's analysis of an experiment proceeds

Micturition and defæcation are also considered under two headings The first type is complete, in a biological sense The cat prospects a site, assumes the appropriate posture and performs the act This response is usually a result of stimulation of the septum pellucidum, rarely in the hypothalamus The second type is that in which excreta are passed without the accompanying posture of the body This is probably because of suddenly increased peristalsis, or bladder contraction, and arises principally from supraoptic stimulation This is because the hypothalamic influence is almost solely on the viscera, whereas more anteriorly somatic movements are coördinated with visceral activity

A further group of responses merit psychophysiological analysis A complex reaction can be elicited which has been named the "attack reaction" which may turn into a "defence reaction," and later be associated with flight A complete picture of a cat preparing to rebuff a dog can be produced by stimulation of points in the periformical region of the hypothalamus This brings into prominence the relation between autonomic activity and the sensation of emotion Experimentally it must be compared to the "sham rage" of decorticate animals Hess regards the attack reaction as a genuine rage, being an instance of an emotion generated purely by subcortical structures

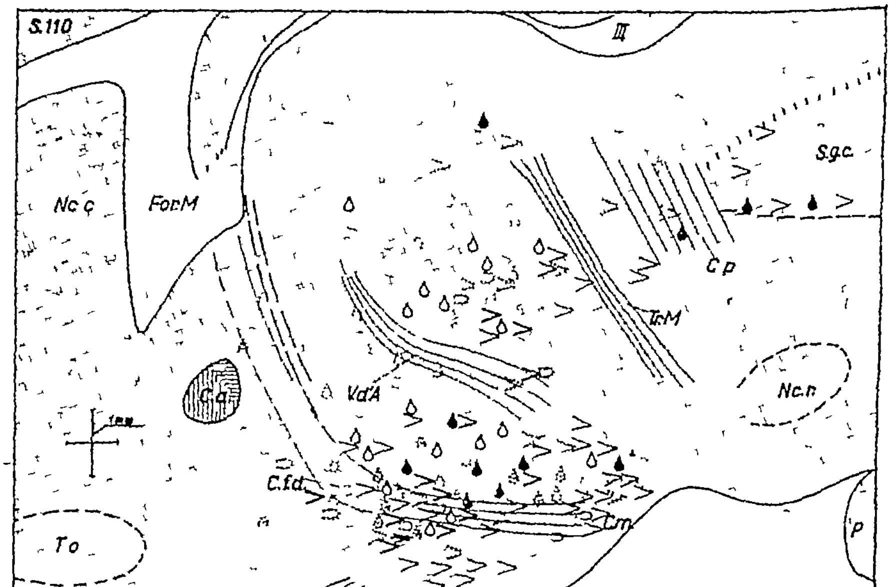
Related responses, caused by more lateral stimulation, are the appearance of abnormal appetites Bulimy, where the cat is apparently so hungry that it will chew any object given to it, or abnormal thirst, where even unpatatable fluids will be drunk, are seen

SLEEP

Finally, there is an all too short discussion of the production of sleep by diencephalic stimulation In Hess's interpretation sleep, as a restorative mechanism, is also a vegetative function, and in the sense of being an inhibition of motor activity it provides a link with the section on somatic functions of the 'tween brain

The production of sleep by electrical stimulation is the most widely known of Professor Hess's findings and has aroused much controversy Ranson and his colleagues, in particular, have asserted that sleep is only produced by destructive lesions and have failed to repeat Hess's results Here, more than anywhere in following the work on the freely moving animal, study of the film records is important

Hess distinguishes three syndromes—true sleep, adynamy, and atony Sleep is a reversible phenomenon, and involves a characteristic posture A cat is asleep (Hess says) when it has curled up in a corner but can be roused by noise, or particularly by putting food near it, afterwards it will return to sleep This only occurs with stimulating anywhere in a broad zone, the *hypnogenous zone*, in the lateral thalamus and subthalamus (at the level of the upper part of the massa intermedia) Atony can be produced by electrical stimulation and is an active inhibition, whereas adynamy, lack of initiative, is due to a locus of destruction in the hypothalamus Adynamic animals show no interest in their surroundings, will flop in any attitude when dropped on to a table, and are quite unrousable These lesions need to be in the *dynamogenous zone* in the hypothalamus, and apart from physical inactivity there is, apparently, a "running down" of the whole organism, with effects such as a fall in body temperature and a fall in the red cell count The difference between adynamy and sleep is as real as that between coma and normal sleep in human patients, and the failure to make the distinction has led to confusion in investigations of the physiology of sleep



A representative conventional diagram illustrating the collected results of stimulating discrete points in the diencephalon. The symbols represent:

> Panting ↄ Vomiting → Sneezing ∪ Salivation

Symbols heavily lined indicate points where the response was obtained with the lowest voltage.

Anatomical landmarks: C.a. anterior commissure; *C.f d* descending column of the fornix; Ch., optic chiasma; C.m mammillary body; C.p, posterior commissure; For M foramen of Munro, *S g.c.* substantia grisea centralis T o., Nc.c. caudate nucleus; Nc.r, red nucleus; P, pons; olfactory tubercle Tr M tract of Meynert; Vd A., bundle of Vicq d Azyr; III th

MOVEMENTS CAUSED BY DIENCEPHALIC STIMULATION

The second section of *Das Zwischenhirn* deals with the somatic motor effects produced by diencephalic stimulation This is of considerable importance because few other workers have paid attention to it, and none have used unanæsthetised animals Only the briefest outline of the findings will be given here, because they need to be analysed in detail to appreciate their full significance

The movements seen comprise a group involving movements of the head—raising, lowering, and rotating—a group in which turning the body to one side is seen, and a group consisting in isolated or combined movements of limbs, vibrissæ, pinna, or face Movements may be synchronous with the rhythm of the stimulus, characteristically seen in the first group mentioned, and presumably involving a simpler, more direct pathway than other effects in which smoothly executed responses showed no relation to the rhythm of stimulation None of the effects were obtained from regions in the hypothalamus proper, they were responses from the subthalamus and thalamus Rotation of the head resulted from stimulating the most anterior and superior field, slightly posterior to it, turning to the same side as the stimulus was seen, while rostro lateral to the rotation field there was turning to the opposite side The most posterior field caused lowering of the head, while raising of the head was obtained from a region somewhat anterior, but more medial and extending inferiorly into the subthalamus There is, however, considerable overlapping of the fields although their efferent tracts are distinct For details of the individual limb movements, &c, reference must be made to the published maps

ERGOTROPE AND TROPHOTROPE

Professor Hess's interest in the autonomic nervous system is not confined to the rôle of the hypothalamus, as is shown by the wide sweep of ideas in *Die funktionelle Organisation des vegetativen Nervensystems* His concept of the ever present activity of this system in maintaining the economy of the body is put forward in detail The interested reader should study the original work, although he must be prepared for hard toil with complex thought in German

The property of autonomous activity without nervous control, which is possessed by all organs in some degree, is discussed in an opening chapter Then follows a short account of the way in which this inherent autonomicity is coordinated, before considering the much more important integration by the peripheral autonomic system Hess considers the vegetative nervous system as composed of the *ergotrope*, and the *endophylactic* or *trophotrope* parts This terminology needs explanation

The concept of two opposing systems has pervaded all work on the subject, the original terms, sympathetic and parasympathetic, were never precise functionally, and became synonymous with the more purely anatomical categories thoracolumbar and craniosacral outflows. With the discovery of the chemical mediation of their effects, the pharmacological terms adrenergic and cholinergic have come into more general use Hess has coined his names to give them functional significance His views are somewhat similar to those of W B Cannon *Ergotrope* indicates organisation for work and external activity and is a function of the adrenergic part of the autonomic nervous system *Endophylactic* (*trophotrope*) signifies organisation for repair of wear and tear, for maintenance This is largely carried out by cholinergic nerves The concept is wider than those usually accepted Sleep, for instance, is a trophotropic function but would not fall within most classifications as a parasympathetic activity Control of respiration is also considered as a vegetative function, which logically it is, in spite of the fact that the respiratory muscles are striated

This part of the book reviews and recapitulates much earlier work on the control of the circulatory system (Hess 1930) and of respiration (Hess 1931, 1938) Hess's observations on the relation of diaphragm *tone* to the extent of inflation of the lungs, and the importance of this in relation to the Hering Breuer reflex mechanisms regulating the character of breathing, should be more widely known

The sensory visceral nerves are included in the discussion of the peripheral autonomic nervous system, this is of interest, because since Langley's original definition there has been a tendency to regard this as a purely efferent, effector system

INTEGRATION

The organisation of the central nervous control of vegetative functions is coordinated at spinal cord level to some extent, is more highly organised at the medullary level, but is supreme in the diencephalon The experimental findings have been detailed above The rôle of the hypothalamus can best be summarised, as Sherrington might have done it, by saying that the " hypothalamus is the head ganglion of the vegetative nervous system " All normal coordinations of autonomic activity is controlled and carried out at this level, in Professor Hess's view

The cerebral cortex can influence this coordination The emotional and visceral responses to external events perceived by the eyes or other senses show that this must be so (see Hess 1925) In the past decade much interest has been shown in the physiological mechanisms underlying this, and many cortical areas have been shown to mediate autonomic activity The fact that electrical stimulation can produce these effects, however, does not prove that it is a normal controlling mechanism Professor Hess is convinced that in fact the normal visceral control is quite unrelated to conscious activity (which is generally agreed) and that this control is exerted from the hypothalamus, or the diencephalon. The cortex can alter the hypothalamic control, but it plays only a small part, just as we know that conscious events, although they can influence visceral activity, play no part in regulating it

Thus an integrated concept of the organisation of the autonomic nervous system emerges For the younger generation of physiologists, impatient for precision but using increasingly artificial preparations, this work of an outstanding researcher of the older generation is exemplary For medical men working by the bedside the work should be an assurance that experimental physiology has not lost its power of integration It can still study the whole animal and, from the very complexity of this approach, derive results that are more directly applicable to understanding the whole patient than many other types of laboratory experiment

We see that most people would rather be fooled than told truths which they do not feel that they can face Hence an economy that is always capsizing and the politics of international anarchy We prefer luxuries to necessities debt to solvency, nationalistic wars to peace Further we see that words have done all they can to caulk the gap in our gaping seams—far more than the last century thought possible With word fantasies ranging from psycho analysis to frank farce we have kept a film of pretence, a play of fun and fairy tale, over the widening fissure But now words are at the end of their tether Their elasticity is worn out, their credit exhausted We have to come back to Thought, to what we really think things to be and not what we say they are or should be '—GERALD HEARD *Morals Since 1900* London, 1950, p 144

Robinson (1943), and the 51% of Dummer (1949) The mother's employment was a factor in only 2 2%, this is very much lower than the figure given by Neale et al (1942) for Birmingham where in 1938 15% and in 1941 11% of mothers abandoned breast feeding because they went to work

THE ARTIFICIAL FOODS USED

The artificial feeds in use were

	No of cases	%
National Dried Milk	268	63
Cow's milk	82	19
Proprietary milk foods	74	18

(Sometimes several of these milk foods were given to the same child on different occasions)

It will be seen that the place of breast milk has usually been taken by National Dried Milk Indeed at 10½*d* for the equivalent of 7 pints of cow's milk it is difficult for mothers to resist its use, though of course it is the same price as the 7 pints per week priority milk for the under fives In Bristol, as elsewhere, it is distributed at infant welfare clinics and private shops, and is very easily obtainable by any mother

SUMMARY

The incidence of breast feeding in Bristol has fallen considerably in the past twenty years In 1949 36 2% of babies were breast fed at three months, compared with 77% in 1929–30

In 1947–48, fewer patients delivered in nursing homes had established lactation at fourteen days than patients delivered at home or in hospital at six months the incidence of breast feeding in these groups was the same

Mothers belonging to the Registrar General's classes I and II appear to breast feed their children longer than mothers belonging to classes IV and V

At six months, the weight of artificially fed babies is more variable than that of breast fed babies, this suggests that breast feeding is preferable for the majority of children

64 4% of mothers weaned their babies because their breast milk failed for no obvious reason only 2 2% because they went to work

National Dried Milk was the food most often used (63%) for artificial feeding Cow's milk was given to 19% of infants, and proprietary brands of milk to 18%

Our thanks are due to Prof A V Neale, department of child health, Bristol University, for his help in the preparation of the questionnaire of the 1947–48 survey, to Prof R H Parry, medical officer of health, City of Bristol, for his advice and permission to undertake the work, to Mr H S Twiggs, deputy city treasurer, and Miss M C M Hooper, of the city treasurer's department, for their help in recording the information on punched cards, to Mr H A Bywater for his help in preparing figures and graphs, to Mr A R Sherman, Miss K G Wright, and other members of the maternity and child welfare department, for their help in the analysis, and finally to the health visitors who made the work possible, and who went to great trouble to complete the special forms required

Measles

During the week ended March 3, 29,154 cases of measles were notified in England and Wales—an increase of 1378 over the previous week, when there was a record incidence The number of cases notified in this biennial epidemic surpasses that of 1943, previously the most severe, by a considerable margin The majority of cases continues to be in the southern part of the country London notified 3315 (3746), Essex 2403 (2094), Middlesex 2246 (2136), Surrey 1869 (1861), and Kent 1503 (1509), the previous week's cases are in parentheses High totals also occurred in the West Riding of Yorkshire with 2540 (2073) and in Lancashire with 2496 (2422), while of the county boroughs Leeds with 498 and Southampton with 446 were most affected

Whooping-cough

Weekly notifications of whooping-cough continue to rise, and during the week ending March 3 the previous record was again exceeded, the 6096 cases in this week exceeded by 168 the number in the previous week During the corresponding week of 1950 notifications totalled 1614 Most cases again occurred in London and the home counties, although in this locality the position improved *somewhat* Totals were London 396, Essex 449, Kent 531, Surrey 293, and Middlesex 341 The first three showed reductions of 29, 49, and 61, but in the last two there were increases of 31 and 49 Notable increases were also experienced in Lancaster with 637 (588), the West Riding of Yorkshire with 390 (307), and Devon with 211 (129), the figures for the previous week are in parentheses In Stafford there was a drop of 97 cases, bringing the total to 208 Liverpool and Manchester, with 141 and 108 cases, had the highest incidence among county boroughs

Influenza

The latest figures show that throughout England and Wales the prevalence of influenza continues to decrease sharply In the week ended March 3, the incidence of influenza deaths per million population in the great towns was 8 58, deaths in these towns totalled 178, compared with 1099, 1239, 1269, 865, 492, and 317 in each of the six weeks from that ended Jan 20 to that ended Feb 24 New claims to sickness benefit under the National Insurance Act numbered 146,200 in the week ended Feb 27, compared with 267,400, 200,300, and 161,600 in the three earlier weeks of the month

Poliomyelitis

In the week ended March 3, notifications of poliomyelitis in England and Wales were as follows paralytic 19 (16), non-paralytic 9 (5), total 28 (21) Thus there was an increase of 7 compared with the previous week, for which the figures are in parentheses Total uncorrected *notifications for the first nine weeks in each of the past* five years have been as follows 1947, 99, 1948, 339, 1949, 178, 1950, 395, 1951, 270

Parliament

Clean Upholstery

In the House of Lords on March 6 Lord Macdonald of Gwaenysgor moved the second reading of the *Rag, Flock and Other Filling Materials Bill* The original Rag Flock Act, he said, was before Parliament 40 years ago in 1911 A similar Bill was passed in 1928 Since then a helpful report had been received from the Merthyr Committee in 1946 But the passing of time had shown that the existing legal safeguards were inadequate The present Bill provided for registration and licensing of premises used for upholstery and kindred activities Registration would take place unconditionally on demand, but no licence would be issued for the making of rag flock for upholstery unless the premises contained adequate appliances for securing cleanliness

Lord Amulree, who was among those who welcomed the Bill, said, however, that this must not necessarily be looked at purely as a health matter It was a strange and curious thing that, as far as he knew, there was no vidence that any sickness or disease had been caused by lling materials which were below the standards here aid down The Merthyr Committee's report said that rom an æsthetic point of view it was repugnant that pholstery should be filled with filthy material What his Bill was intended to do was to ensure that nothing f that sort should happen

Lord HADEN-GUEST said that in his work as a doctor he had seen something of the conditions under which the filling of upholstery and bedding was carried out, and it was alarming The percentage of traders who offended in this matter might not be large, but nevertheless control was necessary The Bill was read a second time

QUESTION TIME

Care of Children

In answer to a question Mr CHUTER EDE, Home Secretary, stated that on March 1 1951, 15 children committed to the care of local authorities were accommodated in remand homes with the Home Office authorisation given under Section 13 (6) of the Children Act, 1948 The normal length of stay of such children in remand homes was about six weeks While he deprecated using remand homes for this purpose, it was necessary to do so as an exceptional measure at present, but the need would disappear as more reception centres were provided under the Children Act

Mr K. P THOMPSON asked if the Home Secretary was aware that this matter was a cause of great disquiet among those concerned with the welfare of this small number of children[1] They were liable to be overlooked because their numbers were small Six weeks in this sort of home could do these children more harm than they would have come to in the place from which they were removed for care and protection.—Mr EDE said he was concerned about this matter, and he was hoping that the new powers given to local authorities and to the Home Office under the Children Act 1948, would be used to reduce this number still further He was afraid, however that even then there might, in some exceptional cases be a necessity for one or two children to be detained temporarily in such places

G P Hospitals

Mr H A MARQUAND, in reply to Sir IAN FRASER, said that according to his present information 9 hospitals in which general practitioners formerly provided, for their own patients, treatment not of a specialist nature had been converted into specialist hospitals or for other uses Specialist staff had also been introduced into a number of small general hospitals where general practitioners formerly provided special forms of treatment, but in many of these, and also in some other hospitals, some beds had been reserved for patients under the care of general practitioners The following was the list of the 9 hospitals

Warde Adam Cottage Hospital South Elmsale Mirfield Memorial Hospital Alfred Bean Hospital Driffield Beverley Dispensary and Hospital Wirksworth Cottage Hospital Staines Hospital, Stanmore Cottage Hospital Epping Cottage Hospital Arundel Hospital

Hearing-aids

In answer to a question Mr MARQUAND stated that 118,699 patients in England and Wales had been supplied with Medresco hearing aids and evidence derived from a recent survey suggested that about 90% continued to use them regularly The services of research development and distribution were so widely spread over various Government agencies that he could not give any useful figure of total costs The manufacturing cost was remarkably low He expected that deliveries to distribution centres would continue at a rate of over 6000 a month during 1951 but some of these would be required for replacements

Checking the Doctor's List

Colonel O E CROSTHWAITE EYRE asked the Minister of Health what reasons prompted him to adopt the policy set out in circular E C L 6 51 dated January 11 1951, for the purpose of eliminating inflation in doctors records—Mr MARQUAND replied The present inflation makes it impossible accurately to assess the total amount of remuneration due to general practitioners or to distribute this remuneration equitably as between one doctor and another Colonel CROSTHWAITE EYRE Why has the Minister adopted this method? Does he realise that in Hampshire alone 26 lorry-loads of documents have to be moved from the food offices to the executive council offices and that neither has enough staff to deal with them? Why could he not have put a simple question in the forthcoming Census which would have given him all the information he needed?—Mr MARQUAND Possibly because the hon and gallant gentleman did not make that suggestion in time

Charge for Road Accident Treatment

Mr HUGH FRASER asked the Minister whether he was aware that anyone suffering a road accident in which a motor vehicle was involved could be charged 12s 6d by hospital management committees for emergency treatment, and what action he proposed to take—Mr MARQUAND replied The liability to meet the charge for emergency treatment under Section 16 of the Road Traffic Act, 1934, is upon the person using the vehicle at the time of the accident Mr FRASER As all people subscribe to the National Health Service today, and anticipate a free service, is it not time this section of the 1934 Act was repealed?—Mr MARQUAND The National Health Service Act expressly states that this section should continue in operation

Number of Medical Students

Mr SOMERVILLE HASTINGS asked the Minister what steps he was taking to augment the present facilities for training medical students and thus ensure a sufficient number of doctors, in view of the necessity for expansion of the National Health Service and of the estimated wastage of members of the medical profession.—Mr MARQUAND replied I am advised that the present output of the medical schools should be sufficient to provide for some expansion as well as to replace wastage, and I am not at present satisfied that any special steps to increase it are required

British Red Cross in Korea

Replying to a question Mr K G YOUNGER, Minister of State for Foreign Affairs, stated that the British Red Cross Society s welfare team was due to leave Japan on March 1 for Korea, where it would assist under the Unified Command in welfare and public health work among the local inhabitants In addition, British Red Cross and St John Naval V.A.D.s were employed on a hospital ship in Korean waters, and the society had made grants to the International Red Cross Committee for relief work in Korea British Red Cross and St John personnel and stores were being used to help Service casualties in hospitals in Japan.

Exemption of Medical Students from Z Reserve Call-up

In answer to a question Mr JOHN STRACHEY, Secretary of State for War stated that no medical students whose studies were approaching completion should be called up under the Z Reserve call up scheme If they should receive a call up notice they might apply for exemption, submitting supporting evidence, and exemption would be allowed

Model By-laws on Hygiene

Mr MAURICE WEBB, Minister of Food replying to a question, stated that up to Feb 25 this year he had confirmed by laws on the handling wrapping delivery, and sale of food which had been made by 1062 local authorities, and he was expecting to take similar action shortly in a further 193 cases He had no information about the remaining 189 authorities

Infant Vaccination

In answer to a question Mr ARTHUR BLENKINSOP stated that the 1946 acceptance rate of infant vaccination was just over 41%, and for 1949 it has been roughly estimated as about 28%

Subnormal Children

In answer to a question Mr GEORGE TOMLINSON, Minister of Education, stated that at the beginning of last year there were approximately 28 000 children in England and Wales known to require education in special schools for educationally subnormal pupils, and there was provision for rather more than 15 000 He intended to do all he could within the limits of available building resources to increase this provision In this way he hoped that it would be possible for more of those educationally subnormal children, who drifted towards delinquency, to be dealt with preventively by special educational treatment

In England Now

A Running Commentary by Peripatetic Correspondents

O what can ail thee, babe in arms,
Perpetually bellowing ?
Hideous is the noise you make
And deafening

O what can ail thee, babe in arms ?
Pipe down, you little so-and-so
Mum says your guts are working fine
—And Mum should know

Your face is anything but pale,
Your urine is a great success,
Throat, abdo, chest, and ears are clear
And C N S

Nurse diagnosed and cured the babe
And silenced his unearthly din
Piercing his buttock she espied
A safety-pin

* * *

The blossom is out once more—not in our rain-sodden gardens, but at the *Daily Mail* Ideal Home Exhibition, which remains open at Olympia until March 31 Here can be seen azaleas, camellias, clematis, magnolias, prunus, rhododendrons, and many other shrubs in full bloom, with bulbs and rock plants at their bases and beside them roses and carnations The gardens as always wake us up from the dull, dreary months of winter, and our thoughts turn from the tiresome controversies of today to the colour, splendour, and peace of a cool summer evening This year the houses in the Village of Ideal Homes have been set off by a central garden. Of special interest among the six houses is that of the Women's Institutes, this house embodies the ideas of 400,000 women who filled in questionaries On an electricity stand a house-parlour-maid and cook are sitting in a kitchen, this tableau will certainly be of historic interest to the younger generation The Fashion and Beauty section supplies sound factual evidence for the advocates of "make-up" There is an excellent demonstration of a new window cleaner, and a well-known product for killing indoor smells strives valiantly but unsuccessfully beside a demonstration of frying There is a new section exhibiting books, where many hundreds can be examined The Royal Air Force shows the improvements in the design and furnishing of their married quarters, while the Army's new barrack block must surely amaze many old and not so old soldiers, as also will the modern private's choice of bedside books In another part of the exhibition the NAAFI show models of some of their clubs

Interwoven into this exhibition are lessons for everyone The police advise about protection against burglary, the Royal Society for Prevention of Accidents teach road sense and manners, and the W V S look after a model of an accident-prone house The Grand Hall is lit by ten chandeliers, and dominating it at one end is a replica of an arch of the Crystal Palace Although there is one exhibit showing the South Bank, it is surprising how little the Festival is in evidence It is still an exhibition of every aspect of home life

* * *

"Darling, isn't 'Cortisone' a sort of linoleum ?"

* * *

Broadcast health talks are all very well, but listeners will keep fitting the wrong caps on their heads or their family's For instance, the best way to reduce one's weight no doubt is to eat less, but some qualifying words of warning are required A little starvation will do no harm to the overweight man or woman of middle age whose fires are beginning to die down, but how about young people ? One cold evening, soon after listening to the talks on fat-reduction, I was visited by the chairman of the parish council, he came ostensibly for a specimen of my signature, but actually to talk about his secretary, a girl of twenty Apart from asthma since the age of two, she seemed healthy until this autumn, when she had pleurisy After that she was repeatedly radiographed and was reported to have a "doubtful shadow" Finally she was pronounced non tuberculous and fit to return to work shortly, though she must come again every month for examination

Mr Chairman wanted to unburden himself about two things One was slimming Like many girls of her age, his secretary was plump but not fat, and—like most of them—she wished she was slim and elegant Having learnt from women's magazines and B.B C talks that the proper way to get thinner is to eat less, she reduced her intake so thoroughly that by the autumn her lunch was down to one rye biscuit and an orange I agreed heartily with my visitor that this was wrong Next he asked whether I thought the girl really had tuberculosis This is one of the awkward and unanswerable questions that people ask when they get a doctor alone, and, as ever, there was more behind it Mr Chairman confessed that his mother died of tuberculous kidneys, and her long and painful illness gave him as a boy a horror of the disease Obviously he does not want a T B secretary, and would be glad of a clearer diagnosis than "We think not, but "

He talked to me because no doctor in the Health Service ever seems to have time to listen Laments of this kind reach me from all sides "My doctor never explains anything Can you tell me why ?" or "The doctors are always run off their feet these days and I don't like to bother them" They catch me when I am out for a walk or posting letters at windy corners, they grab me as I pass their garden gate, confide in me over shop counters, or whisper in my ear at parish council meetings The worst (except for the windy corners) is when they telephone An unknown woman rang me up last week and talked about her distressing problem for about five minutes before she drew a breath and I could interrupt to ask, "Why are you telling me all this ?" Her only reply was, "Mrs X said you might be able to advise," and then she started off again. Mentally anathematising Mrs X, a doctor s grass widow and a friend of mine, who should have known better, I listened for ten to fifteen minutes and spent another five persuading the voice that, willing as I was to help her, the right person to consult was her own doctor, whom I knew to be kind and sensible even if overworked

Now that much of the old family doctor relationship has gone, many people are feeling the lack of someone they can talk to about the health problems which overflow into their daily lives My G P colleagues give me the reverse side of the picture When they are so rushed that there is no time for any but snap diagnoses, they clearly cannot listen to long tales of their patients' worries and give them the reassurance and common sense advice which is all that most of them want

It is easy to see why the radio talks and newspaper and magazine articles on health are increasingly popular But though many of these are ably constructed, easy to understand, and correct in substance they cannot take the place of the spoken interview, with question and answer and mutual consideration of the individual situation How would it be if those of us who are no longer physically fit to join actively in the fray were given an official niche—like a citizens' advice bureau, only more medical—where we could do some weeding out and lighten a little the burdens of both our overworked colleagues and our anxious fellow citizens ?

* * *

The scene was the medical outpatients department of a children's hospital, where a mother had brought her small daughter because she had fits After eliciting a long family history of fits the registrar asked whether there was any backwardness in the family Like a flash came the reply "Aye, Doctor, her sister comes down the stairs backwards"

* * *

"Who is arranging the funeral, Mrs Jones ?"

"The Co op They do it ever so nice, doctor, and you get your divi too"

Aphorism of the Week

Colostomies are easier opened than closed

Letters to the Editor

THEORY OF CEREBRAL LOCALISATION

SIR,—The paper in your issue of March 3 by Dr Gooddy and Mr McKissock propounds, if I understand it aright, some strange beliefs Its authors seem to hold that neurological theory inclines to, or even insists on, an absolutist hypothesis of cerebral function, which they demand should be abandoned forthwith.

Those who have had the chance of reading Dr Gooddy's earlier paper[1] will know that the idea of an absolute functional topography, as though the living brain were engraved with the neat labels and figurines so familiar in textbooks, is a spectre which most perplexingly haunts him , and it now appears that he has persuaded Mr McKissock into joining him in his torment It must be emphasised, however, that such a doctrine is quite foreign to the thought of serious neurologists, whether they be physician or surgeon, physiologist or anatomist Indeed, it is doubtful whether it has ever been an acceptable tenet, though Ferrier probably came near to holding it The teachings of Hughlings Jackson contain nothing that could be so interpreted, for he argued that the clinical experiments of disease upon cerebral physiology indicate primarily not a functional, but a symptomatic, localisation Sherrington is equally blameless For example, in writing[2] of the excitable cortex, the "so called motor area," he specifically comments that "the student looking over the political map of a continent may little realise the complexity of the populations and states so simply represented We looking at the brain chart of the textbook may never forget the unspeakable complexity of the reactions thus rudely symbolized and spatially indicated" Latter day writers are also free from guilt Thus Denny Brown and Botterell[3] have lately recorded their conviction that "the phenomena of electrical excitation of the cortex demonstrate an important and localised motor effect, rather than a specialised motor act" In other words, this is the expression of a strictly empiricist attitude, applicable *mutatis mutandis* to all aspects of cerebral physiology

Having delivered their initial onslaught against what I submit to be a non existent doctrinal error, Dr Gooddy and Mr McKissock then apparently fall swiftly into the very heresy they have been attacking They write of the re allocation of functional sites and fancifully imagine the peregrinations of a centre concerned with reading, for all the world as though they themselves believed "centres" and "functional sites" to have a real and absolute existence, and not to be simply convenient abbreviatory terms, which in use briefly imply a host of more or less well known empirical facts Having next reminded us of the self evident proposition that the retention of a function necessarily indicates the preservation of the anatomical substrate requisite for its performance, they proclaim that any form of experimental approach to determine the situation of the structures involved must be forgone as "reactionary"

This egregious ukase evidently stems from over great timidity in face of the truism that the appearance of a certain disability after a particular anatomical lesion does not mean that the function of the locus injured is in health merely to prevent that defect They do not seem to realise the corollary—that the normal function of a part is always something positive, and never a mere negation, a device for warding off disorder To exemplify this if a wretch should lose both eyes he is blind, but only the very tortuous would choose to assert from this that the eyes are to prevent blindness, instead of accepting the everyday verdict that their use is to see Or again, the man in the street knows that his kidneys are to make water with , it takes the most vile addict of modern "scientific medicine" to protest the negative hypothesis—that they are only to prevent uræmia To give a final example nearer home, the use of the precentral gyrus is not to prevent paralysis, nor yet as some perhaps once thought to beget movement , rather it provides a facilitating mechanism by means of which we practise all those delicate motor skills, both major and minor, of which Dr Gooddy himself has written so lyrically elsewhere

Perhaps, after further reflection, Dr Gooddy and Mr McKissock will be more leniently inclined towards the exercise of experimental techniques However, that may be, they can at least console themselves with the thought that repetition of "methodological postulate" is a most excellent clinical test for dysarthria

Birmingham MICHAEL JEFFERSON

ÆTIOLOGY OF CHRONIC GASTRIC ULCER

SIR,—I am interested to learn from Professor Bentley and Dr Barlow (Feb 24) that there is no difference in the vascular density of the lesser curve mucosa as compared with that lining the rest of the stomach in cases of gastric ulcer

As far as I am aware, a differential analysis of the number of vessels to the square inch of mucosal surface in normal and abnormal stomachs has not been published I assume, therefore, that Professor Bentley and Dr Barlow are speaking from personal experience I would like to ask two questions Is their opinion based mainly upon specimens removed at routine post mortem examinations and at operations for chronic duodenal ulcer, or exclusively upon those removed in the treatment of chronic gastric ulcer ? In a "normal" stomach, and in the stomach of a patient with a duodenal ulcer, there is little difference between the vascular density of the lesser and greater curvatures Secondly, if their material was solely from cases of gastric ulcer, was the mucous membrane dissected off the underlying structures before being micro radiographed ? In a recent paper from the department of surgery at Newcastle upon Tyne, by Mr Key,[1] no mention of this step is made, and the surface radiographs illustrated are of the full thickness of the stomach wall The vascular density of the mucosa can hardly be assessed in such a film Only surface films of the lesser curve are shown Moreover, his description of the comparison between the "vascular pattern" in the normal and the abnormal is drawn from transverse sections , in which plane the difference in the vascular density is not apparent

The risk of artefacts occurring with injection methods is well recognised, and I mentioned it in my article The lower density of the lesser curve in cases of gastric ulcer may prove ultimately to be an artefact , but the simple technique employed is unlikely to have been the main factor To draw conclusions from quantitative variations between different preparations is hazardous, as Professor Bentley and Dr Barlow correctly assert , but to draw conclusions from quantitative variations occurring in individual specimens is quite sound, because it is unlikely that the conditions of the injection would vary between different areas of the same stomach. Only the various regions of each organ were compared , in no instance was the mucosa of one specimen compared with that of another Moreover, as the observation consisted of a relative difference between the vascular density of the mucosa on the lesser and greater curvatures, the efficiency of the mucosal filling is of secondary importance The difference between two weights can be detected without knowing the absolute weight of either

To compare various areas of one preparation is always safer than comparing the same area in various preparations, because, as Professor Fisher[2] points out, "careful control" in experiments may be fallacious owing to the tacit assumption that the experimentor knows all the factors which might influence the result, which is seldom the case

Bromsgrove, Worcestershire F S A DORAN

FOOD WORKERS AND INFECTIOUS-DISEASES REGULATIONS

SIR,—The Catering Trade Working Party refers in its report[3] to the Public Health (Infectious Diseases) Regulations, 1927, and in paragraph 75 advocates their *modification to include within their scope excretors of* food poisoning organisms—a very desirable change Further it is suggested (paragraph 74) that advice can be given to those found in hospital to be carriers of enteric and dysentery and discharged as such, "*to avoid employment in the catering trade*" So far so good But then the report proceeds "if a Medical Officer of Health thinks it necessary in order to prevent the spread of infection he should take statutory action under the P H (I D) Regs —E & W 1927, Scotland 1932—if the worker is a carrier" It is my submission that unless the worker is *already* engaged in the food trade the M O H cannot take any statutory action

The relevant paragraphs are in part III of the first schedule to the regulations The first refers to a "case," which by the wording of paragraphs 1 (i) (*a*) and 1 (ii) must be in a person already engaged in the food trade since clearly the person *specified* in the notice referred to in section 1 (i) (*a*) *cannot discontinue* an occupation unless he has already *begun* it, and it would be idle to address the notice referred to in paragraph 1 (ii) to the patient or relatives, &c, unless the patient is the food worker The second *paragraph refers to a* suspected "carrier" already engaged in the food or drink trade In both cases the procedure is slow, involving a report to the local authority and action by that body (notice of restriction of employment) With regard to the case, the notice of restriction applies until revoked, with regard to the carrier, the notice is for a defined period

Now the regulations are presumably framed for the protection of the public, and also with a view to their usefulness in dealing with recalcitrant persons We know that in 99% or more of cases there is no need to invoke them formally But on the other hand they *may* be necessary, and the powers *may* be needed in a hurry Most of us would agree that typhoid or paratyphoid carriers, or suspected cases, should not work in food preparation, &c Yet we cannot under the present regulations exclude them (if they object) *at once* but only after the local authority has agreed Secondly we cannot require any carrier to abstain from *entering* such an occupation (but only require him to discontinue if he is already in it) We must wait till the risk has been *run before we take the obvious precautionary steps* It will be remembered that strict compliance by the medical officer of health and the local authority with the regulations is necessary in such an important matter affecting a person's livelihood

I maintain that

1 The medical officer of health should have immediate suspensory powers in respect of suspected cases and carriers of dysentery, typhoid, paratyphoid, and food poisoning occupied in a trade or business concerned with the preparation or handling of food

2 The authority should have powers to require, until revocation of the notice known carriers of these diseases to abstain from any occupation concerned with the preparation or handling of food or drink intended for sale for human consumption whether then engaged in such an occupation or not

These suggestions were made in 1949 in a note by Dr T G Galvin and myself on an outbreak of paratyphoid fever[4] It is simple enough to procure protection for the worker (*a*) by a compensation clause operative in the event of unreasonable action by the medical officer of health, and (*b*) by right of appeal to the courts

The consideration of compensation for workers for loss of earnings referred to in paragraph 68 of the *report* might also be extended to contacts *temporarily* excluded for examination, &c In my presidential address to the Yorkshire branch of the Society of Medical Officers of Health in 1946 I made reference to this[5] To some extent the point has been met by the Ministry of National Insurance (acting I believe on Dr J Grant's suggestion at the York meeting of the county borough group of the Society of Medical Officers of Health in 1947), which allows benefit equal to the ordinary sickness benefit *on certification* by the medical officer of health, but is this quite enough ?

There is a further point not referred to in the report. At present there is mounting public anxiety about open cases of tuberculosis being allowed to handle food for sale for human consumption

If the regulations are to be modified, as they should be, it is to be hoped that these considerations will be borne in mind

E D IRVINE
Exeter Medical Officer of Health.

LARYNGEAL VERTIGO

SIR,—Your leading article of July 15 prompts me to describe the following case

A plethoric, obese, European man, aged 49, with deeply nicotine stained fingers and cheery countenance, was warded with bronchitis and emphysema During a *bout of coughing* he fell off his bed and cut his nose He had been *sitting on* the edge of the bed and had reached the stage in the paroxysm of having "no breath left" in his chest when he lost consciousness He came round a second or two later on the floor, and was helped up by the dresser who witnessed the attack. He had soft arteries and a blood pressure of 135/90 mm Hg Skull, nervous system, blood sugar, and urine examinations were negative He admitted to a cigarette consumption of not less than forty a day and a beer intake of ten pints a week, but he did not consider he was a heavy eater

Questioning revealed two previous attacks, with an interval of three months, while working in the Middle East The first occurred, when he was sitting "having a beer with a friend," at the end of a paroxysm of coughing, he sustained a bruised neck from the table edge The second occurred when he was walking away from the lunch table His newly lit cigarette precipitated a bout of coughing ending in his pitching forward unconscious, sustaining lacerations on his face Extensive hospital investigations were then made, apparently with negative result

Is it not possible that such attacks in this well defined group of patients are due, not to any particular anatomical or pathological peculiarity, but rather to the *fact that* these people are, next to those with whooping cough, the most prone to the type of coughing bout which may end in syncope ? Might not the mechanism of these attacks be comparable to the sudden loss of consciousness *that may take place during* vomiting ? This is, I believe, a *fairly common* phenomenon In recent experience I recall a man, aged 28, who lost consciousness for a few seconds during a bout of vomiting from food poisoning, not associated with significant fluid loss Another example was a young woman, otherwise in *robust health*, who had *three* times *fainted* in the act of vomiting Diaphragm and glottis activities during vomiting must produce intrathoracic pressure changes and consequent events akin to those suggested in your leading article

A preferable name for the syndrome might be "paroxysmal post tussive syncope" It might then be possible to rescue the condition from the limbo of the larger ear, nose, and throat textbooks, and to reduce the number of patients who are at present worried by their label of "epileptiform attacks" without the reassurance that is possible with accurate diagnosis

UNFAIR QUESTIONS

SIR,—Those of us whose duties involve teaching are sometimes astonished at questions set in examination papers or asked in viva voce examinations For instance, in a recent final examination in surgery one of the five questions required the candidate to discuss the surgical complications of typhoid fever In the last last ten years at Guy's Hospital only 4 cases of typhoid fever have been admitted and none of them had surgical complications A surgical colleague who is particularly interested in intestinal ailments tells me that he has never encountered any surgical complication of the disease It seems then that in a qualifying examination such a question is needlessly academic The surgical textbooks in common use among students contain only the briefest mention of the surgical complications of typhoid fever—certainly not enough to enable a student to write a reasonably good answer

The following question was set in a paper for a higher qualification in medicine "Discuss the diagnosis *in a young woman* presenting herself with the complaint of double vision" The italics are mine, but even without them the candidate is surely entitled to infer from the wording that the examiner had in mind certain conditions in which the patient's sex is important in diagnosis So far I have not found any physician who can give an adequate explanation

Again, is it reasonable to expect candidates to memorise the doses of large numbers of drugs, many of which are not commonly used? Surely to try to remember doses is not only unnecessary but dangerous In promotion examinations in the Services candidates are provided with the official books normally available to them, such as *King's Regulations* and the *Manual of Military Law* Why not allow candidates for examinations in the clinical subjects to consult the *British Pharmacopœia* or even the *National Formulary*? It is perhaps only fair to say that the examiners who most often ask doses are not clinicians

London, S E 1
J J CONYBEARE

A C T.H IN THE DIAGNOSIS OF GOUT

SIR,—The diagnosis of gout, up to the present, rests on clinical assessment, a history of intermittent attacks, a family history of the disease, a raised plasma uric acid and normal hæmoglobin levels, rapidity of change in the sedimentation rate X ray appearances, and the therapeutic test with full doses of colchicine Even consideration of all these factors will sometimes leave the diagnosis in doubt

In 1949 Hellman[1] and Wolfson[2] showed that, between the third and sixth day of administration of adrenocorticotropic hormone to gouty subjects, there was a "low corticoid" phase and this was often associated with an exacerbation of the disease By giving 150 mg A C T H daily for four days Hellman provoked an attack in 3 out of 5 trials in typical cases in the interval phase On the other hand, Gutman,[3] using 100 mg daily for four days in 5 interval gout cases on a low protein diet, only produced 1 attack in 8 trials

Early last year we observed in hospital 3 cases of typical gout Each patient was given a "shock" dose of 100 mg A C T H in an interval phase, to see whether an acute attack would occur during the low-corticoid phase regularly enough to make administration of A C T.H a useful test for gout Only 1 patient, however, had an acute attack within a week of the injection, and this was on the sixth day Four hours after the injections of A C T H there was a drop in the circulating eosinophils and lymphocytes, with an increase in the number of polymorphonuclear cells, together with a rise in plasma cholesterol level and a slight fall in plasma uric acid There was an increase in urinary uric acid and 17 ketosteroids, involving the crude, ketonic and β fractions, during the period of A C T H administration

In view of the failure of A C T H alone to cause regularly an exacerbation of gout, a further patient was first given 300 mg A C T H spread over twenty-four hours—with no effect except that she stated that she felt better in herself than she had for years After ten days she was put on a ketogenic high purine diet, containing 66 g carbohydrates and 263 g fat, and given 1 0 g purine (largely in fish roes) After three days she was given another 300 mg A C T.H and the diet was continued for four more days This combination of ketogenic high purine diet with shock dosage of A C T.H again failed to provoke an attack of gout

The failure of these attempts in 4 classical cases makes us think this method unlikely to be of value for excluding the presence of gout

SUPPRESSION OF DIGITALIS-INDUCED VENTRICULAR PREMATURE BEATS BY A NEW PROCAINE DERIVATIVE

SIR,—Recently 'Pronestyl' (procaine amide hydrochloride) has been introduced for the treatment of ventricular arrhythmias, injected intravenously it has proved successful in cases of paroxysmal ventricular arrhythmia not yielding to other drugs, and also in cases of ventricular premature beats induced by cyclopropane anæsthesia

Pharmacologically the new compound has notable advantages over procaine Its central stimulating effect is less than 40% of that from procaine Whereas procaine is fully hydrolysed in blood plasma at 37°C within six minutes, hydrolysis of the amide amounts to $7^1/_2$% in nineteen hours under the same conditions, and in the body the plasma level of this substance falls only 10–15% per hour Thanks to its stability, oral administration is fully effective

In a case of coronary disease we applied the new drug with probably life saving effect, to control intolerance to digitalis glucosides due to numerous ventricular premature beats

The patient a man aged 50, had had manifestations of coronary disease for seven years The electrocardiogram showed the pattern of an old large anterior wall infarction, although there was no clinical history of this event The pulse rate was constantly 100 or more per min., with premature beats arising from two ventricular foci, their number varied at different times from a few up to 50 per min Radiologically the heart was notably enlarged to both sides. In the past six months the patient had also had recurrent phlebothrombosis of the left femoral vein, and during the second attack a severe pulmonary embolism occurred After a critical illness the patient recovered, but signs of increasing heart-failure appeared left hydrothorax, liver engorgement, pretibial œdema of both legs lumbar œdema, and dyspnœa on the slightest exertion Pulmonary embolism took place twice more, the emboli probably originating in the heart since no phlebothrombosis was discovered in a thorough search The second embolism gave rise only to slight and transient manifestations, but the third although far less severe than the first was serious

---

[1] Hellman L *Science*, 1949 109, 280
[2] Wolfson W Q *J lab clin Med* 1949 33 1473
[3] Gutman A B Yu T F *Amer J Med* 1950 9 211

Before the first pulmonary embolism the patient received 0 20 mg digitoxin daily with some benefit, although even with this minimal dosage the number of premature beats rose slightly, with 0 30 mg they became so frequent that the pulse rate actually increased With a change to other digitalis glucosides the result was the same, and thus digitalis administration in sufficient dosage was prevented After the first embolic episode, however, and simultaneously with the heart failure, complete intolerance to digitalis developed, so that even the small dosage previously tolerated gave rise to numerous ventricular beats with an increased pulse-rate With mercurial diuretics it was not possible to compensate for the lack of digitalis, and after the third pulmonary embolism the situation of the patient again became critical, owing to the steadily progressing heart failure

In an attempt to suppress the stimulating action of the digitalis on the ventricular foci from which the extrasystoles were originating, 2 5 g pronestyl was administered daily with 0 40 mg digitoxin This met with full success Within a fortnight, under this treatment combined with mercurial diuretics twice a week, complete compensation was achieved The side effect of the digitalis on the rhythm was almost entirely eliminated—only a very few premature beats were present from time to time—and the glucoside could now be given in a dosage never before tolerated which produced a sufficient inotropic action and slowed the pulse rate to 80 per min. The patient has now resumed his professional work on a reduced scale

It should, however, be borne in mind that pronestyl has not the same effect on auricular premature beats

Anglo-Swiss Hospital, Alexandria Egypt. FR MAINZER

CONGENITAL SYPHILIS IN A FIJIAN

SIR,—Stitt[1] states that amongst the Pacific Islanders a relative immunity to syphilis is found in spite of repeated exposure to infection from syphilitics of other races In Fiji syphilis is widespread amongst Indians and part Europeans, but it is doubtful if the disease has ever been recorded in a pure Fijian, though Lambert[2] quotes (without clinical details) one case described to him by Harper The following is a description of a case of congenital syphilis in a pure blooded Fijian

A Fijian girl, aged 23, of pure Fijian descent, born in the Tailevu district of Viti Levu, denied infection with yaws in childhood At the age of 13 she came to live in Suva, where she remained throughout the war In 1945 she was admitted to the Colonial War Memorial Hospital, Suva, where the Kahn reaction of her blood was found to be ++++ She received a total of 3 0 g neoarsphenamine and was then discharged Though unmarried she was living with a pure blooded Fijian when she became pregnant for the first time, and was admitted to the obstetrical annexe at the hospital on Aug 27, 1950, suffering from an antepartum hæmorrhage Shortly after her admission she was delivered of a macerated male fœtus, the placenta was removed manually as it was adherent The Kahn reaction of her blood was still ++++ After 4 injections of neoarsphenamine she absconded

Microscopically the placenta was fleshy Microscopical examination showed extensive fibrosis, endarteritis, and loss of blood vessels from the villi—all typically syphilitic changes The fœtus was almost full term and was well macerated Section of the liver stained by Levaditi s method showed numerous spirochætes indistinguishable from those of *Treponema pallidum*

It is generally admitted by authorities that no case of congenital yaws has ever been observed (Stitt[3]) yaws is said to be neither hereditary nor congenital[4] The present case therefore appears to be one of acquired syphilis in a Fijian girl with congenital syphilis in her offspring, and this indicates that there is no racial immunity to syphilis in Fijians

In the absence of racial immunity, the rarity of such a syphilitic infection must be ascribed to an acquired immunity It is thought that infection with yaws in childhood confers relative immunity to syphilis Should this immunity become less pronounced, then syphilis could be as readily acquired by Fijians as by other races

In the many Fijian women now attending the antenatal clinic at the Colonial War Memorial Hospital in Suva the Kahn reaction of the blood is often found to be negative It is therefore probable that, owing to the efficient control of yaws which has been established, many Fijian girls are never infected with it in childhood. The girl in question evidently escaped infection in early life, but was then exposed during the war years to syphilitic infection in Suva

In planning extensive anti yaws campaigns amongst primitive people, consideration should be given to the possibility that their immunity to syphilis might thereby be destroyed

I have to thank Dr J M Cruikshank, Inspector-General, South Pacific Health Service, for permission to publish this case

THE FALSE "ACUTE ABDOMEN"

SIR,—In his letter of Jan 13 Dr H M Royds Jones quotes a paper which Le Marquand and I wrote five years ago[1] We described a series of cases which clinically simulated perforated duodenal ulcer, instead of operating immediately we observed them for a few hours and we were rewarded by a complete change in the clinical picture with spontaneous recovery Dr Royds Jones describes a series which also recovered rapidly and spontaneously He then proceeds to discuss our paper he writes that we described an "epidemic of Bornholm disease" Reference to our article will show that we were not, at the time, convinced that we were dealing with an epidemic, we considered many possible explanations but Bornholm disease was not among them We suggested that the syndrome may have been due to a *forme fruste* of perinephric infection However in the course of time I have modified my own opinions perinephric infection does, in a transient phase, mimic the "acute abdomen," but this explanation cannot be stretched to cover all the cases we described I believe now that our series was a minor epidemic, but I cannot allow these cases to be labelled as Bornholm disease

The original epidemic of Bornholm disease occurred on the Danish island of Bornholm, and the main features observed were severe fleeting pain and rigidity of muscles innervated by the thoracic part of the cord Since the work of Lewis and Kellgren[2] we know that lesions of almost any deep structure will elicit the response of rigidity and pain in the muscles of its segment With the march of time Bornholm disease will prove to have been an all embracing title for many different lesions (their theoretical limit is equal to the total number of deep structures within the thoracic nerve territory multiplied by the total number of their pathogens!) Scientifically the diagnosis of Bornholm disease should command as little respect as, for example, the diagnoses of sciatica or rheumatism Certainly we must acknowledge that there are epidemics of severe transient pain and rigidity in the great trunk muscles, but these epidemics must be due to many different causes Dr Royds Jones's case histories are consistent with my speculations He is to be congratulated on a series of observations, under difficult conditions, extending over twenty three years

Suspected ulcer perforation was once an immediate signal for operation The possibility of a "false acute abdomen" as discussed in this correspondence, should give pause for thought There is now further additional argument against great haste to operate the work of

---

[1] Goldstone B W Le Marquand H S *Lancet* 1946 ii 207
[2] Lewis, T Kellgren J H *Clin Sci* 1939 4, 47

Hedley Visick,[3] later amplified by Hermon Taylor [4] and by Stead,[5] suggests that some cases of perforation are better treated conservatively It should also be realised that very early cases are in a state of acute shock, lately Selye [6] has defined this phase in more precise biochemical terms, calling it the "damage phase of the alarm reaction" It is, of course, the wrong time for operation Twenty-seven years ago Pannett [7] was teaching this, he instanced the case of a man who perforated on the steps of the Royal Free Hospital. At first it was a matter for congratulation that he was rushed to the theatre within an hour, but he died soon after a straightforward operation. There are many obstacles which delay the progress of the "acute abdomen" from his home to the operating-theatre. One may speculate that these irritating difficulties must have saved thousands of lives

BERNARD GOLDSTONE

VACCINATION AGAINST SMALLPOX

SIR,—Commenting on my letter published in your issue of Feb 10, Dr Millard (Feb 24) writes 'I am also in favour of such people being inoculated against typhoid, but I do not think it necessary that everyone in this country should be similarly inoculated." I did not suggest that, because Dr Millard favours vaccination of all who visit the East, he should therefore advocate universal vaccination, but pointed out that, taking his argument to its logical conclusion, the vaccination of such travellers would increase the number of undetected cases of smallpox among them

Dr Millard's main argument against vaccination was that it is liable to render attacks so mild and atypical that they pass unnoticed and constitute a danger to others. He then recommended vaccinating the very people most likely to bring the disease into the country There is surely an inconsistency here. At the same time Dr Millard would leave unprotected those who remain at home and will be exposed to infection from the unrecognised case of smallpox in the vaccinated traveller It is difficult to imagine a policy more calculated to increase the number and severity of epidemics

Arlesheim
Switzerland.

A. M WOOLMAN

SIR,—Dr Millard's delightfully provocative article raises the question whether variola minor and variola major are the same disease and caused by the same virus

For the last six years in the Upper Nile province of the Sudan we have had a slowly developing epidemic of variola minor, with about 270 notified cases and 5 deaths The disease was at first regarded as chickenpox, but after a few reported deaths it was diagnosed as variola major Vaccination campaigns were organised, but because of the nature of the country they were largely ineffective and vaccination was abandoned as soon as the disease was recognised as variola minor The infection spread through the province slowly by traceable tribal contacts On two occasions laboratory tests proved it was variola and not chickenpox. The clinical aspect of the cases, and the slow spread, gave the epidemic a totally different picture from that of variola major

The epidemic occurred in a comparatively primitive community of 80,000 people in an area of 90,000 sq miles, and the number of cases notified was probably less than half the total. In one area where we instituted quarantine the people asked us not to do so because they knew that the disease was different from variola major and conferred immunity against variola major in fact they welcomed its appearance

Contrast this slow epidemic with one seen in 1947 in a similarly primitive population at Yirrol in the Bahr el Ghazal province, where there were 280 cases with 117 deaths It was a flare up, rapid in growth, killing in its severity, and again rapid in its decline—thanks mainly to an intensive vaccination campaign

In the Upper Nile outbreak we abandoned vaccination on advice from laboratory specialists, and because climatic conditions and communication difficulties made it impossible to guarantee the supply of lymph vaccine *regularly* and in an *active* state In some areas, owing to such difficulties, we had less than 15% "takes."

I think there can be little doubt that there are two different diseases, both clinically and epidemiologically, and that the viruses are different The distribution of the rash is the same, and the rash is in one stage, but in variola minor it is less profuse, and not so confluent in the axillæ and the groin, though confluent cases occur with facial distributions. The patient is not so seriously ill when the rash is in its pustular stage as in cases of variola major The differentiation between variola minor and chickenpox is often difficult unless care is taken to examine the extremities and the rash itself Generally mistakes are made most when the prodromal rash is not regarded as such, and the main disease is missed.

The immunological reactions between vaccinia virus and the various geographical strains of the variola minor virus also vary [1] There is yet no evidence to prove that variola virus strains change their virulence the major runs true to type, and so does the minor virus The differences are evident epidemiologically and clinically variola minor gives a negligible mortality, rarely reaching 3% compared with 20–30% for variola major. I suggest that the two diseases are entirely different entities, and that to confuse the two is to confuse the whole issue

Dr Millard's note that in the past inoculation used to be resorted to, and that inoculation was preferably from serious rather than mild cases is of historic interest In the Sudan in the 18th century inoculation was also practised. A piece of rag was tied round the arm of a serious case and its price was haggled over The person to be inoculated eventually bought it, having a guarantee not to get more than so many pocks If he had a severe attack he claimed his money back, if he survived Possible explanations are that the virus had "burnt itself out" in the serious case, or that the patient's reactions had reduced its virulence

MUNCHAUSEN'S SYNDROME

SIR,—A further example of the Munchausen syndrome was recalled to my notice today when a query arrived from the Royal Victoria Hospital, Folkestone, about a man treated here last April. A few days after his irregular discharge from the Western Infirmary, Glasgow, early in May, 1950, he was admitted as an emergency to the West London Hospital.

This man is 23 or 24, Irish, and of somewhat prognathous appearance He claims to be aspiring to the priesthood, and his complaints usually take the form of bleeding from nose, eyes, ears and urinary tract along with great pain of a renal-colic type He has a rooted objection to cystoscopy or catheterisation, the threat of which leads to a demand for discharge No cause can be found for his bleeding but sharp instruments may be found in his bed, and many of the blood-stained sites show no bleeding point. He tends to ascribe his symptoms to trauma before admission, and is admitted following collapse in the street

I should be most interested to know if he has been an inmate of other hospitals. I feel sure that he has been in many in the past nine months.

Western Infirmary
Glasgow

LYSIVANE AND ARTANE IN PARKINSONISM

SIR,—Dr Garai's conclusions (Feb 24) are most interesting My experience has been that 'Artane' is much more effective in postencephalitic parkinsonism than in the idiopathic and arteriosclerotic varieties, and Dr Garai's findings support this Of 31 postencephalitic patients 7 (23%) showed no improvement, whereas of 18 patients suffering from idiopathic and arteriosclerotic parkinsonism 6 (33%) were not improved

The large doses used by Dr Garai invite comment I find that where artane is effective, improvement is apparent on the second or third day [1] Where this does not occur, persistence with the drug is unlikely to result in success. Canelis et al [2] noted improvement within three days, continuing up to the end of the second week Dr Garai writes "it was found necessary in most cases to exceed 50 mg before full benefit was obtained" Was this the optimum dose, and was the benefit so obtained any the less when this was reduced to 20 mg or less daily ?

I agree that amphetamine has a potentiating effect on artane, especially in the control of oculogyric crises Where the number and severity of these is not satisfactorily reduced by artane alone, the addition of amphetamine may bring about the desired effect

CAFESTOL IN RHEUMATOID ARTHRITIS

SIR,—In their letter of a year ago, Ferrari and Allegri [3] reported good results with 'Cafestol,' a new preparation obtained from the unsaponifiable fraction of the seed of *Coffea arabica* L , in 16 patients with polyarthritis due to rheumatic fever, rheumatoid arthritis, ankylosing spondylitis, or degenerative arthritis of the spine The beneficial effects were more evident in the acute inflammatory disorders than in the degenerative Pain was rapidly diminished and there was progressive reduction in the articular swelling, temperature, and erythrocyte sedimentation rate (E S R) A steroid configuration has been ascribed to this vegetable substance, which Ferrari and Allegri claim to have the same clinical applications as the most potent steroids of animal origin, such as 'Cortisone' Their letter gave only a brief preliminary report without any clinical or experimental details

Cafestol is manufactured in Italy and marketed by Messrs Simes, of Milan So far we have not obtained any literature on the pharmacological or clinical aspects of this substance However, we received 3000 mg of the original substance, as marketed in Italy, for clinical trial, in addition to 3000 mg of a British substitute prepared especially for research investigations The Italian preparation was dissolved in olive oil, whereas the British substitute was dissolved in propylene glycol, and both were packed in ampoules containing 100 mg In view of these very limited supplies the investigation has been made on two patients only, each preparation being used entirely on one patient

Italian Cafestol

A married woman aged 45 had had rheumatoid arthritis for 22 years The onset was afebrile, insidious, and polyarticular There was no family history of rheumatism Five days before this trial began, the patient was admitted to hospital as an urgent case because of a sudden relapse, both hands, knees, and ankles being painful swollen and tender Radiography of her hands showed that she had stage 3 rheumatoid arthritis, according to the Steinbrocker classification [4] After clinical and laboratory investigations she was given 400 mg of cafestol intramuscularly daily for three days, and then 200 mg daily for nine days, making a total of 3000 mg After this her joint pains were slightly less, movements of the affected joints were a little easier, and the range of movements was slightly greater The pain in the knees, which was severe at the beginning of the course, became much less by the end of the course, and there were no new sites of pain. The laboratory findings (see table) show no significant changes in the E S R., packed-cell volume, plasma viscosity, or serum levels of sodium, potassium, or chlorides

LABORATORY FINDINGS

Date 1950	Blood: E S R *	Blood: P C V (%)	Blood: Plasma viscosity	Blood: Eosinophils per c mm	Serum levels (mg per 100 ml): Sodium	Serum levels (mg per 100 ml): Potassium	Serum levels (mg per 100 ml): Chlorides	Urinary ketosteroids (mg per 24 hr)

In both cases daily intramuscular injections were begun on Dec. 6

* Spa hospitals method corrected rate

On the fifth day of the injections the patient complained of intermittent nausea which had begun soon after she started the injections and had got worse each day She did not vomit at any time She also complained of a "persistent taste of chlorodyne," which became less intense on the fifth day Visiting relations and fellow patients all said they could smell chlorodyne in her breath, but we could not detect the smell. So far as could be ascertained, she had not eaten or drunk anything containing chlorodyne or similar substances, and so far as we know, none is present in cafestol This symptom became less pronounced on the day after the daily dose of cafestol was reduced from 400 to 200 mg Nothing abnormal was detected in the urine, and no explanation can be offered for the curious statements

At the end of the course the patient appeared to be happy, full of optimism and generally improved, in spite of the negative laboratory findings

British Substitute

A young unmarried woman, aged 22, had had rheumatoid arthritis in the interphalangeal joints of both hands for 2 years The onset was afebrile, insidious, and polyarticular, the hips, ankles, elbows, and shoulders being affected in turn She had been in hospital for six weeks when the present trial was begun All her interphalangeal joints and both wrists were swollen and painful, with much restriction of movements Radiography showed a stage 2 rheumatoid arthritis. The left acromioclavicular joint was also involved She walked with pain and some difficulty There was no family history of rheumatism The eosinophil count (80 per c.mm) showed no response to adrenaline

She was given 400 mg of the British substitute for cafestol intramuscularly daily for three days, followed by 200 mg daily for nine days, making a total of 3000 mg During the course there was a gradual reduction in her joint-pains and she became much more cheerful

At the end of the course she had improved slightly, more particularly as regards pain, but it would be hard to say whether the improvement was greater than might have been expected from her condition before the course The laboratory findings (see table) showed no significant changes

Both these patients showed some clinical improvement, mainly in a diminution of their pain The improvement was slightly greater in the patient given the Italian cafestol, but the results were much less definite than one might have expected from the letter of Ferrari and Allegri [3]

It was unfortunate that only such a small amount of cafestol was obtainable

We wish to thank Messrs British Schering Ltd, for supplying the cafestol and the British substitute
